About this Document

Welcome to RAD-Series AAA Server software. This guide provides information about:

- Server components and operation
- Server Manager configuration
- Advanced server configuration, including:
  - EAP authentication
  - External data stores
  - Advanced Policy
- Server and accounting logging and monitoring
- Format and content of RAD-Series Server configuration files

Audience

This Administrator’s Guide is for Network and Systems Administrators who must configure and maintain the RAD-Series Server. It assumes that you:

- Are familiar with basic Unix commands
- Know the hardware and software profiles of the server machines and other devices used throughout the network
- Are familiar with LDAP or Oracle configuration, if implemented
- For wireless networks, know the EAP methods and user name formats used

Notational Conventions

Text in this guide is marked in different styles to denote various things.

<table>

Introduction

Overview

See the RAD-Series Getting Started Guide for installation and basic configuration instructions.

The Interlink Networks RAD-Series Server software provides Authentication, Authorization, and Accounting services to secure wired or wireless networks. It uses the RADIUS protocol for LAN access control and supports:

- Password Authentication Protocol (PAP)
- Challenge-Handshake Authentication Protocol (CHAP)
- Microsoft® Challenge-Handshake Authentication Protocol (MS-CHAP), v1 and v2
- Extensible Authentication Protocol (EAP)

The RAD-Series Server fully implements the IEEE 802.1X standard for securing wireless LANs using Extensible Authentication Protocol (EAP). EAP authentication may be done using any of several different methods. See page 18 for a list of supported EAP methods.

The RAD-Series Server also supports:

- Proxying authentication and accounting messages to another RADIUS server
- Redundant LDAP or Oracle® user data stores, including load balancing and failover functions
- SNMP integration
- DHCP relay from configured IP address pools
- Token pools to control access to resources
- Advanced Policy to implement:
  - DNIS routing
  - Dynamic Access Control
  - Authorization based on logical groups
  - Customer-defined policies to apply to RADIUS requests
Software Components

The RAD-Series Server software delivered to you includes:

- RAD-Series Server application supporting RADIUS protocol
- Server Manager administration console
- Remote Control

You may have additional components, depending on your license option.

RAD-Series AAA Server

RAD-Series AAA Server application is comprised of:

- Finite State Machine (FSM) and some associated routines
- Software modules
- Configuration files

When the RAD-Series Server is started, it loads and initializes the software modules and reads the configuration files.

Finite State Machine

At the core of the RAD-Series Server is the Finite State Machine (FSM) and associated state tables that define all processes for handling RADIUS requests. At application startup, the FSM reads instructions from a state table (by default the `radius.fsm` text file). The state table outlines what modules to call in response to certain events and in what order to call them.

The RAD-Series Server comes with a default state table capable of, with no modifications, handling standard RADIUS and EAP requests. However, you can extend or customize server function just by modifying the default state table or creating new state tables. For example, you can log interim accounting messages by calling the appropriate predefined module at a certain point in the accounting handling process.

The FSM also provides the flexibility to call custom plug-ins created with the Software Developers Kit (SDK) in lieu of the standard server modules.

Software Modules

RAD-Series Server software modules define the actions that the server performs in response to FSM events--such as authenticating requests, authorizing service, and logging. Built-in actions support various extensions, such as authenticating users with information retrieved from replicated data stores.

To customize the RAD-Series Server with a proprietary software module, you must build and compile your plug-ins using the Software Developers Kit (SDK), which is purchased separately.
Configuration Files

The configuration files store application-specific information used by the software modules to process requests. Most configuration parameters are modified through the Server Manager, although some RAD-Series Server features can only be configured by using a text editor. The files you’ll most commonly work with are:

- **aaa.config** - defines all RAD-Series Server properties.
- **authfile** - defines realm datastores.
- **decision files** - contain advanced policy information for user authorization and session control based on any logical group that can be defined with attribute-value (A-V) pairs.
- **dictionary** - defines all attributes and values that may be used to build A-V pairs recognized by the RAD-Series Server. These A-V pairs convey information in requests and responses. This file also contains definitions for all the authentication types that the server recognizes.
- **EAP.authfile** - defines realm authentication actions.
- **las.conf** - enables session tracking and specifies some session timing and management values.
- **log.config** - defines accounting message logging behavior.
- **radius.fsm** - is the Finite State Machine table. You can edit this to reorder RAD-Series Server processing steps or call custom plug-ins.
- **realm files** - contain user profile entries, including check, deny, and reply items.
- **users** - defines user profiles which can be used for exceptions to the normal realm based configuration. The default **users** file contains only the test_user entry after an initial installation.
- **vendors** contains optional entries for vendor names and numbers.

Server Manager

Server Manager is a browser-based application for configuring and managing RAD-Series Servers (all servers must be running the same version) on local or remote machines. It can also be used to view or print server and accounting logs. Server Manager has two main components:

- Server Manager program
- Java graphical user interface

The Java interface can be customized for your application by using the Server Manager API, which is part of the *Software Developers Kit*.

Server Manager requires the Java Run-Time Environment (JRE) installed on each administrator workstation from which you will access it. See the *Getting Started Guide* for more information.
Remote Control

The Remote Control program contains the Java RMI objects that facilitate communication between remote RAD-Series Server and the Server Manager program. You only need to install this component on server machines that do not have Server Manager installed.

How the RAD-Series Server Works

RADIUS Message Exchange

The RAD-Series Server and its clients communicate through an exchange of RADIUS messages (data packets) that contain information related to a user request. Different types of RADIUS messages are exchanged throughout the AAA process.

When the server receives a request, it first validates the access device that sent the request, then the user. If the access device is permitted to send requests to the server, the RAD-Series Server software takes information from the Access-Request message and attempts to match the request to a realm user profile store and a user profile. The realm policies and user profiles specify conditions that must be met to successfully authenticate and authorize a user. If an EAP authentication method is used, the server and the client exchange a series of Access-Challenge messages to verify the user’s credentials.

If authentication is successful, the server goes on to authorization. Authorization may verify other information, such as the port number of the access device. If all conditions are met, the server sends an Access-Accept packet to the access device. An Access-Accept data packet includes attribute-value pairs that specify the type of user service and other session information, such as a timeout value that indicates when to disconnect the user.

If at any point conditions are not met, the server will send an Access-Reject message and the access device will disconnect the user.

When the access device receives an Access-Accept packet, it may send an Accounting-Request message to the server to start logging the session. The Accounting-Request data packet describes the type of service being delivered and the user that will use the service. The server responds with an Accounting-Response message.

During the session, the access point and the server may exchange Accounting messages that provide “Interim-Updates” to verify that the session is still active.
RADIUS message exchange with EAP authentication
RADIUS Message Format

RADIUS requests and replies are transported by UDP. By default, the RAD-Series Server listens on UDP port 1812 for Access-Requests and port 1813 for Accounting-Requests.

EAP-enabled access devices use the EAPOL (EAP Over LAN) standard format for transporting EAP messages within RADIUS messages. EAP requests and responses are encapsulated in the RADIUS EAP-Message attribute of the RADIUS messages. EAPOL also provides control functions such as start, logoff, and key distribution.

Password Encryption

The User-Password attribute within RADIUS messages are hidden using the RADIUS MD5 hashing algorithm.

Shared Secrets

RADIUS servers and their clients maintain a trust relationship through the use of a shared secret. A shared secret is a string up to 1023 characters long, with no spaces. The same secret is configured on both the server and the client device. A server may share a different secret with each of its clients.

Attribute-Value Pairs

RADIUS messages are primarily composed of attribute-value (A-V) pairs. A-V pairs represent a variable and one of the possible values that the variable can hold. A-V pairs are exchanged in RADIUS messages to:

• Match values when authorizing an Access-Request (check and deny items)
• Add provisioning instructions or other messages to an Access-Accept data packet (reply items)

In an RAD-Series Server configuration file, the A-V pairs usually follow the syntax:

AttributeName=Value

A-V pairs also appear in the server accounting logs (Merit format) where they follow the syntax:

AttributeName:Type=Value

Request Processing

When the RAD-Series Server receives any RADIUS message, it calls the FSM and defines a starting event according to the type of message. This first event will determine the first action. The following diagrams show how the default FSM calls actions to process requests for authentication, authorization, and accounting. This process can be modified by editing the FSM table or by creating custom plug-ins to replace the standard actions.
**Authentication**

The authentication process verifies that the access device and the user are legitimate.

1. The access device sends the RAD-Series Server an Access-Request containing the User-Name from which the Server get the user ID and realm.

2. The RAD-Series Server checks for the user’s profile in the default users file and if found uses it to authenticate the user.

3. If the username is not found in the default users file then the RAD-Series Server finds the realm’s user profile storage entry in the *authfile*.

4. The RAD-Series Server authenticates the user according to the protocol established by the realm’s authenticator entry in the EAP.authfile.
   
   If PAP, CHAP, or MS-CHAP is used, the RAD-Series Server searches the user data store for a matching user profile.
   
   If an EAP method is used, authentication will be carried out according to the EAP method (MD5, PEAP, TLS, TTLS, AKA, SIM etc.).

5. If authentication succeeds, the server proceeds to authorization. If authentication fails, the server sends an Access-Reject message to the access device, who disconnects the user.

---

**BASIC (non-EAP) authentication process**
Authorization

The authorization process determines what services can be extended to the user. The RAD-Series Server can authorize users through several methods:

- On a user-by-user basis with check and reply items
- Based on realms through its Local Authorization Server (LAS) functions
- Based on other logical groups through stored POLICY decisions (advanced policy) that make use of more sophisticated checks and conditional reply items.

1. The RAD-Series Server evaluates the request against any check and deny items stored with the user profile. For example: a check item indicating that the request must be from port 1 on the access device must match a corresponding `NAS-Port=1` A-V pair in the request for the request to be accepted.

2. If there is a `Policy-Pointer` attribute from the user or realm profiles, the server evaluates the authorization policy specified by the `Policy-Pointer` attribute.

3. If all conditions are met, the server sends an Access-Accept message back to the access device.
   
   If any conditions are not met, the server sends an Access-Reject message back to the access device, which disconnects the user.
Authorization flow in default Finite State Machine
Accounting

During operation with session tracking enabled for the realm, the RAD-Series Server tracks information received in Accounting-Requests from the client in an active session table. When the session is stopped, the session record is written to the accounting log file. The predefined accounting logs follow the Interlink-MERIT format. To some degree, you can modify:

- Where and in what format the RAD-Series Server generates the logs by editing the log.config file.
- When the logging occurs by editing the FSM table.

1. The access device sends an Accounting-Request to the RAD-Series Server to start recording the session.

2. The server checks the log.config file for the realm’s logging format.

3. The server begins tracking the session and sends an Accounting-Response to the access device to confirm this.

4. During the session, the access device and the server may exchange Accounting-Alive (Accounting-Interim-Update) messages to verify that the session is still active.

5. The access device sends an Accounting-Request message to the server to stop recording the session, which the server acknowledges with an Accounting-Response.

6. The server writes the session record to the accounting log.
Accounting Process
WLAN Security

With support for IEEE 802.1x functionality, the RAD-Series Server provides security framework to support EAP authentication mechanisms for Wireless Local Area Network (WLAN) users. The RAD-Series Server:

- Authenticates wireless users with password or non-password based mechanisms
- Supports dynamic key generation for data encryption between the access point and wireless stations

EAP Authentication

If the Access-Request message sent to the RAD-Series Server indicates an EAP authentication method for this user, an EAP conversation is encapsulated within the RADIUS exchange that allows mutual authentication to take place directly between the user and server without intervention by the access device. Mutual authentication may be achieved by challenges and responses or exchanging certificates.

1. The access device sends the RAD-Series Server an Access-Request containing the encapsulated EAP Identity Response message.
2. The Server checks for the user profile in the default users file and if found uses it for step 4.
3. If the username is not found in the default users file then the server finds the realm’s user profile storage entry in the authfile.
4. The server issues its EAP challenge to the user and verifies the response.
   - The EAP module searches the user data store for a matching user profile.
   - The server sends an Access-Challenge with an encapsulated EAP message to the user via the access point. There may be several such exchanges.
5. If authentication succeeds, the server proceeds to authorization.
   If authentication fails, the server sends an EAP-Failure to the supplicant and an Access-Reject message to the access device, which disconnects the user.
EAP authentication using a single-phase challenge
Tunneled EAP Authentication

The TTLS and PEAP methods establish a tunnel for secure message exchange. In these methods, the authentication process is divided into two phases:

Phase 1: Secure communication is established between the realm user and the RAD-Series Server.

Phase 2: Actual user authentication is performed.

Separating these operations also provides flexibility. For example, with TTLS you can proxy the authentication requests to a remote RADIUS server. This enables you to provide wireless access to users whose profiles are stored on a legacy RADIUS server that does not support EAP.

In TTLS and PEAP there is a server certificate but there is no client-side certificate to exchange, making it easier to administer a large number of users.

Tunneled methods often have an outer realm user, which is associated with the tunnel itself. This outer realm and “anonymous” user is configured with its own identity separate from the many inner realm users who are authenticated through the tunnel. In some cases (most PEAP implementations), the “outer” tunnel realm and the inner authentication realms bear the same name and there is no “anonymous” user.

1 The access device sends the server an Access-Request containing the encapsulated EAP Identity Response message. This message usually contains information for the outer realm user.
2 The server finds the tunnel realm’s authenticator entry in the EAP.authfile.
3 The server authenticates the outer realm user.
4 If authentication succeeds, the server establishes a tunnel to the user machine.
5 The user sends an Access-Request message through the tunnel containing the actual user information.
6 The server finds the inner realm’s user profile storage entry in the authfile.
7 The server authenticates the actual user. This may utilize a second EAP method, such as EAP-MD5.
   • The EAP module searches the user DataStore for a matching user profile.
   • The server and user exchange Access-Challenges with encapsulated EAP messages through the tunnel.
8 If authentication succeeds, the server proceeds to authorization.
   If authentication fails, the server sends an EAP-Failure to the supplicant and an Access-Reject message to the access point, which disconnects the user.
TTLS authentication
## Preparing the WLAN

A WLAN requires you to synchronize items on the supplicant, access point, and the RAD-Series Server. The following table lists the items you need to synchronize on each node.

<table>
<thead>
<tr>
<th>Item</th>
<th>Nodes</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shared Secret</td>
<td>Access Device</td>
<td>The shared secret configured on the access device and server must match for the two to communicate. Use the Access Devices link to configure this item on the RAD-Series Servers.</td>
</tr>
<tr>
<td></td>
<td>Server</td>
<td></td>
</tr>
<tr>
<td>EAP Support</td>
<td>Access Device</td>
<td>Most access devices require you to enable EAP. You do not need to specify an EAP method, but you must enable support for EAP.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EAP Method</td>
<td>Client Supplicant</td>
<td>Verify that the supplicants support the EAP methods the RAD-Series Server supports. Enable EAP on the supplicants. Configure the same EAP method on the supplicant and the server. Use the Local Realms link to configure this item on servers.</td>
</tr>
<tr>
<td></td>
<td>Server</td>
<td></td>
</tr>
<tr>
<td>EAP Tunnel Realm</td>
<td>Client Supplicant</td>
<td>Required for TTLS. Verify the supplicant has an anonymous user configured on it and configure a tunnel realm for that anonymous user on the RAD-Series Server. For example, if supplicant's anonymous user is: <a href="mailto:anonymous@tunnel.com">anonymous@tunnel.com</a>, you should configure a realm for: tunnel.com. You must configure tunnel realms for TTLS. Configuring tunnel realms for PEAP is optional. Use the Local Realms link to configure this item on the server.</td>
</tr>
<tr>
<td></td>
<td>Server</td>
<td></td>
</tr>
<tr>
<td>Users</td>
<td>Server</td>
<td>The RAD-Series Server must have access to a repository with information for each user. The server supports several different methods for retrieving user information. Server Manager can administer user information stored locally in realm flat files. Use the Users link to administer the default set of users. Use the Local Realms link and select the users icon to administer a specific set of Users associated with a realm.</td>
</tr>
<tr>
<td>Client Certificate</td>
<td>Client Supplicant</td>
<td>For TLS only. The digital certificate identifying the client</td>
</tr>
<tr>
<td>Client CA Certificate</td>
<td>Server</td>
<td>For TLS only. Used by RAD-Series Server to authenticate client certificates. Use the Server Properties link and select Certificate Path Properties. In the Certificate Authority Path field, configure the location of the client CA certificate on the server.</td>
</tr>
</tbody>
</table>
Choosing an EAP Method

Choose EAP methods based on your security requirements and the clients you support.

First, create an inventory of the wireless clients you support. Wireless clients need specific supplicant software for each EAP method (WLAN access devices must only support EAP). You must use supplicants that support the hardware platforms, operating systems, and WLAN cards in your environment. Ideally, you should try to use client hardware and software that allows you to use one EAP method for all your wireless clients. This may mean avoiding solutions that are proprietary or support only a small variety of clients.

Next, determine which of the following features are important to you:

1. Dynamic Key Exchange—Distributes a user-specific encryption key to the client and access device during the authentication process. Without this feature, all clients must share the same static encryption key.

2. Mutual Authentication—Protects against unauthorized (rogue) access points by allowing clients to authenticate the network they are connecting to.

3. Password-based Authentication—Clients provide a password to authenticate to the network. Typically the password is sent to the server in a hashed (one-way encrypted) form. If you are integrating with an existing password storage format, be sure the EAP method you chose is compatible with the password storage format. For the most flexibility, choose an EAP method that allows the RAD-Series Server to access the password in clear text (for example, the PAP password format). Storing passwords in clear text requires you to use EAP methods that encrypt the channel between the client and the access point (like TTLS or PEAP).

4. Digital Certificate/Token Card-based Authentication—Uses a token card, smart card, or digital certificate assigned to each user for authentication. This feature must be deployed in an environment with supporting infrastructure—for example, an organization with a PKI and user-specific certificates.

5. Encrypted Tunnel—Establishes an encrypted channel to securely deliver authentication messages and encryption keys. The encrypted tunnel encapsulates another EAP method that provides the actual user authentication. Encrypted tunnels are good for securing authentication methods that are vulnerable when not encapsulated in an encrypted tunnel.

</thead>
<tbody>
<tr>
<td>Server CA Certificate</td>
<td>Client Supplicant</td>
<td>For TLS, TTLS, and PEAP only. Used by clients to authenticate the server certificate.</td>
</tr>
</tbody>
</table>
### Supported EAP Methods

The following table lists the EAP methods the RAD-Series Server supports and which of the above features each method offers. Use the table and your inventory information to help decide which EAP method to use.

<table>
<thead>
<tr>
<th>EAP Method</th>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TTLS</td>
<td>1, 2, 3, 5</td>
<td><strong>Tunneled TLS</strong>: Can carry additional EAP or legacy authentication methods, like PAP and CHAP. Integrates with the widest variety of password storage formats and existing password-based authentication systems. Supplicants available for a large number of clients. May use PAP, CHAP, MS-CHAP, or EAP-MD5 for inner realm authentication.</td>
</tr>

</tr>
</tbody>
</table>

**Note**: If you are using TLS, TTLS, or PEAP, be sure you configure the required digital certificates after you configure all your realms.
**Process for Securing WLANs**

Below is the general process for using the RAD-Series Server to secure your WLAN. See the following sections of this guide for procedures explaining each of the steps.

2. If the RAD-Series Server is remote, add the server to the Server Manager’s Managed Servers list. See “Adding Servers” on page 30.

3. Load the RAD-Series Server configuration into Server Manager. See “Loading Configurations into Server Manager” on page 39.

4. Identify the access devices that will send access requests to the RAD-Series Server. See “Defining Access Devices” on page 41.

5. Configure tunnel realms if you are using TTLS. See “Defining Realms” on page 50.

6. Configure user authentication realms and user profile data stores. See “Defining Realms” on page 50.

7. Configure user profiles to identify each user accessing services through the RAD-Series Server.
   - If you are using local realm files or the default users file, see “Defining Users” on page 65.
   - If you are using an LDAP directory, see “Using an LDAP Server” on page 127.
   - If you are using an Oracle database, see “Using Oracle® Database” on page 134.

8. Configure digital certificates if you are using TLS, TTLS, or PEAP. See “Administering Digital Certificates” on page 60.

9. Deploy the configuration by:
   - Saving the configuration to one or more RAD-Series Servers. See “Saving Configurations” on page 40.
   - Stopping and starting the RAD-Series Server program. See “Server Administration” on page 32.
Understanding Server Manager

Server Manager is the browser-based application for remotely managing your RAD-Series Servers. It provides administrator access to configuration, administration, and monitoring functions from any networked workstation with an Internet browser.

This section describes the Server Manager graphical user interface. It shows how to:
- Use the Server Manager navigational elements
- Select servers for configuration and administration

There are also instructions for reconfiguring the Server Manager:
- Administrative User Name and Password
- UDP Port Number
- Java Connector type (may use an SSL connection)

Navigating in Server Manager

The Server Manager screen contains four principal work areas:

1.  
2.  
3.  
4.
1. Navigation frame

The Navigation frame on the left of the screen lists the tasks you can perform on the selected servers. Clicking one of the links opens the corresponding page in the Workspace frame.

2. Server Status frame

The Server Status frame, located beneath the Navigation frame, allows you to select the RAD-Series Servers to be managed before executing commands in the Workspace.

The icons next to each server indicate its current status.

- Server Manager cannot connect to the administrative agent (RMI object) on the RAD-Series Server.

- the RAD-Series Server is running.

- the RAD-Series Server is not running.

3. Workspace frame

The Workspace frame is the main work area for the Server Manager. The content of this frame changes depending on the task you’ve selected from the Navigation frame.

For some tasks, pop-up dialogs appear above the Workspace frame for entering additional configuration parameters, for example, when configuring realm entries and setting LDAP directory attributes.

4. Message frame

The area below the Workspace frame displays the results of administrative operations, such as starting and stopping the RAD-Series Server.

The Secure LAN Advisor

The Secure LAN Advisor is an HTML tutorial/help system in the Server Manager GUI that walks you through the tasks for securing WLANs with the RAD-Series Server. The Secure LAN Advisor provides information only—it does not edit configuration files. Follow the Secure LAN Advisor while using Server Manager to create and deploy configurations for securing WLANs.
Configuring Servers through Server Manager

Server Manager provides a temporary workspace for editing configurations. As you work, changes are stored in local temporary files before being saved to the actual RAD-Series Server configuration files. There is only one set of temporary files in Server Manager, reflecting the server configuration that was last downloaded.

To configure your RAD-Series Servers in Server Manager, you’ll:

1. Select managed RAD-Series Server(s).
2. Load the configuration files from a single RAD-Series Server.
3. Edit the configuration as necessary.
4. Save the new configuration to the selected RAD-Series Server(s).
5. Stop and start the RAD-Series Server(s) to activate the new configuration.
Managing Multiple Servers

The RAD-Series Server Status frame in the lower left corner of the Server Manager screen shows a list of managed servers. This list enables you to see the current status of the servers, as well as to select them for administration.

**Note:** The 8.1 Server Manager can only manage 8.1 RAD-Series Servers. If one of the servers configured for management is a different version, it will show a ⚔️ in the Server Status frame and not be usable.

Check the server in the Status frame to select it before executing commands in the Workspace.

Use the Server Manager Administration page to execute basic RAD-Series Server commands. You can also use this page to change the server startup settings or reset the log files.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Options</th>
<th>Help</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Start the RAD-Series Server</td>
<td></td>
<td></td>
</tr>
<tr>

<td>RAD-Series Server Time</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Server Manager can be used to view active session data, read RAD-Series Server and accounting logs, and view server statistics. See “Maintenance” on page 93 for more information.
Configuring Server Manager

Certain features of the Server Manager program can be reconfigured in a text editor.

Changing the TCP Port Number

Server Manager uses two TCP port numbers to listen for information from the workstation browsers:

- Port 8080 for non-SSL (http) connections
- Port 8443 for SSL (https) connections

Port 8080 is enabled by default. To switch ports or to change either port number:

1. In a text editor, open the file server.xml (in /opt/tomcat/conf by default).
2. Locate the lines:
   
   ```xml
   <Connector className="org.apache.coyote.tomcat4.CoyoteConnector"
   port="8080" minProcessors="5" maxProcessors="75"
   enableLookups="true" redirectPort="8443"
   acceptCount="100" debug="0" connectionTimeout="20000"
   useURIValidationHack="false" disableUploadTimeout="true" />
   and:
   <Connector className="org.apache.coyote.tomcat4.CoyoteConnector"
   port="8443" minProcessors="5" maxProcessors="75"
   enableLookups="true"
   acceptCount="100" debug="0" scheme="https" secure="true"
   useURIValidationHack="false" disableUploadTimeout="true" />
   ```
3. To switch from port 8080 to port 8443 (for SSL), see “Configuring Server Manager for SSL” on page 26.
4. To change port numbers, change each instance of “8080” or “8443” to the port number you wish to use.
5. Save and close server.xml.
6. Stop and restart Server Manager.
Changing the Shared Secret

Information exchanged between RAD-Series Servers and the Server Manager program is validated by a shared secret. This secret must be the same for all RAD-Series Servers connected to the Server Manager.

1. In a text editor, open the file `gui.properties` (in `/opt/tomcat/webapps/aaa/WEB-INF` by default).
2. Find the line:
   ```
   rmi.config.secret = <current secret>
   ```
   Replace `<current secret>` with the shared secret you wish to use.

   **Note:** In `gui.properties` and `rmiserver.properties`, the backslash character, ‘\’, must be used as an escape for any special characters in your secret.

3. Save and close `gui.properties`.
4. For each RAD-Series Server you have installed, repeat steps 2 and 3 for the file `rmiserver.properties` (in `/opt/aaa/remotecontrol` by default).
5. Stop Server Manager and Remote Control.

Changing the User Name and Password

To change the Server Manager administrative user name or password:

1. In a text editor, open the file `aaa-users.xml` (in `/opt/tomcat/conf/` by default).
2. Find the lines:
   ```
   <tomcat-users
   <!-- You can NOT use &, <, [, "", :, ;, \, space, tab or control characters in username and password -->
   <user username="uuuuuuuu" password="pppppppp" roles="adminaaa"/>
   </tomcat-users>
   ```
3. Change “uuuuuuuu” to the username you wish to use.
4. Change “pppppppp” to the password you wish to use.
5. Save and close `aaa-users.xml`.
6. Stop and restart Server Manager.
Configuring Server Manager for SSL

To secure data passed between the RAD-Series Server Manager program and your administrator workstations, we strongly recommend that you implement a Secure Socket Layer connection (https). Using SSL requires that, on the Server Manager host machine, you:

- Create a keystore containing a new certificate
- Configure Server Manager for SSL

Create a Keystore and Certificate

The keystore is a repository file that contains keys and certificates. If you do not have an existing keystore, you’ll need to create one and add a certificate for SSL to it.

You can create a certificate with the `keytool` utility included with the JDK. Refer to the JDK documentation for more information.

1. Change directory to the Java bin directory (`/opt/aaa/java/bin` by default).
2. Run `keytool`.
   
   ```
   keytool -genkey -alias tomcat -keyalg RSA -keystore Keystore-path
   ```

   For `Keystore-path` enter the full path of an existing keystore or specify a new one.

3. Follow the prompts to provide information about the keystore and certificate.
   - The final prompt asks for the certificate password. Make up a password and note it for use in `server.xml`. You can press Enter at this prompt.
   - The keystore will be created in the location you specified.
**Edit Server.XML**

1. In a text editor, open the file server.xml (in `/opt/tomcat/conf/` by default).
2. Locate and uncomment the following lines by deleting <!-- and -->:
   ```xml
   <!--
   <Connector className="org.apache.coyote.tomcat4.CoyoteConnector"
     port="8443" minProcessors="5" maxProcessors="75" enableLookups="true"
     acceptCount="100" debug="0" scheme="https" secure="true"
     useURIValidationHack="false" disableUploadTimeout="true"
     >
   <Factory className="org.apache.coyote.tomcat4.CoyoteServerSocketFactory"
     keystoreFile="<the keystore path specified when you ran keytool>>"
     keystorePass="<the password specified when you ran keytool>>"
     clientAuth="false" protocol="TLS" />
   </Connector>
   -->
   ```
3. Edit the keystoreFile and keystorePass parameters. For example:
   ```xml
   <Factory className="org.apache.coyote.tomcat4.CoyoteServerSocketFactory"
     keystoreFile="/opt/aaa/java/lib/security/mykeystore"
     keystorePass="topsecret"
     clientAuth="false" protocol="TLS" />
   ```
   You can optionally change the TCP port number by replacing 8443 with the number you wish to use.
4. Comment out the Connector block for port 8080 by inserting <!-- and --> before and after it.
5. Run `shutdown.sh` (in `/opt/tomcat/bin` by default) to stop Server Manager.
   Make sure it has stopped before proceeding. Recent browser activity may cause this take some time.
6. Run `startup.sh` (in `/opt/tomcat/bin` by default) to restart Server Manager.
Starting Server Manager

On the machine where you’ve installed Server Manager:
1. Open your terminal window.
2. Change directory to /ServerManager_Directory/bin (/opt/tomcat/bin by default).
3. Run startup.sh.

If the process fails to start:
4. Check the log file catalina.out (in /opt/tomcat/logs by default).
   If you see the message “Root cause - Address already in use,” the default port 8080 is already being used by another process.
5. To identify the process currently using port 8080, at your shell prompt, enter:
   
   ```bash
   for i in `ls /proc`; do pfiles $i 2>/dev/null | grep AF_INET | grep "port: 8080" ; if [ $? -eq 0 ];then echo "Is owned by pid $i"; echo ; fi; done
   ```

6. Either change the Server Manager port or kill the process using the port.

Stopping Server Manager

To stop the Server Manager program:
1. Open your terminal window.
2. Change directory to /ServerManager_Directory/bin (/opt/tomcat/bin by default).
3. Close any browser currently connected to the Server Manager or the shutdown performed in the next step may take a long time.
4. Run shutdown.sh.

Starting Remote Control

Remote Control is installed on remote RAD-Series Servers to connect them to the Server Manager interface. This program must be started on the host machine before you can use Server Manager to connect to the server. On each remote machine where you’ve installed Remote Control:
1. Open a terminal window.
2. Change directory to the /remotecontrol_directory (default is /opt/aaa/remotecontrol).
3. Run rmistart.sh.
Accessing Server Manager

Once the Server Manager program is started, to access the graphical user interface:

1. Open your browser and enter the URL `http://IP-address:Port/aaa` where:
   - `IP-address` is the IP for the machine that hosts the Server Manager program.
   - `Port` is the port number assigned to Server Manager. Default is 8080.

2. Enter the Server Manager username and password you choose at installation.
   You’ll see the Server Manager Administration page.

3. If this is the first time you’re accessing Server Manager, enter the user name and password again to authenticate to the Java Run-Time Environment.
   You’ll see the Server Manager Administration page, with localhost listed in the Status frame.

**Tip:** Bookmark this page in your browser for ease of access later on.

If you see a Java run-time error in the Status frame, the workstation may not have the Java Run-Time Environment installed or the second Java logon box may be hiding behind some window, awaiting your entry.
Managed Servers

Server Manager utilizes the Remote Control program installed on the RAD-Series Servers in your network to form a Java RMI connection to them. Once Server Manager connects to an server, it is listed among the Managed Servers. You can download and upload configuration and log file data or issue RAD-Series Server commands.

This section shows how to:
- Add RAD-Series Servers to the list to be managed through Server Manager
- Change managed RAD-Series Server profiles
- Delete RAD-Series Servers from the Managed Servers list

Adding Servers

All RAD-Series Servers managed by the Server Manager are shown in the Server Status frame in the lower left corner of the screen. Follow these steps to add a server to the list.

*Note:* The server installed on the same machine as the Server Manager is automatically added as localhost. It uses the loopback (local) address 127.0.0.1.

1. In the Navigation frame, click Managed Servers.
2. Click the Manage New Server link.
3. On the Add Server page, enter the server’s:
   - Name — label to identify the server in Server Manager
   - Fully-qualified Domain Name or IP address
4. Click the Create button.

The RAD-Series Server’s name appears in the Status frame, along with its status.
Modifying Server Profiles

You can change the name, domain name or IP address for any RAD-Series Server currently listed in the Server Manager Server Status frame. You can also modify RAD-Series Server start options for those servers already in the connected state.

After a RAD-Series Server has been connected, the Managed Server:Modify Server page shows a list of installation directories under Server Properties. These paths must match the server’s actual file directories.

1. In the Navigation frame, click the Managed Servers link.
2. On the Managed Servers page, click the server name link.
3. Modify the fields as necessary.
4. Click the Modify button.

Deleting Servers

To remove an RAD-Series Server from the Managed Servers list:

1. In the Navigation frame, click the Managed Servers link.
2. Click the button next to the server name.
3. Click Delete to confirm the deletion.

The server name should disappear from the Managed Servers page and the Server Status frame.
Server Administration

This section shows how to issue commands to:

- Start and stop the RAD-Series Server
- Change the server’s startup options
- Restart the server after changing configurations, without stopping the service
- Report on server status
- Change the options for the status check program
- Report on server time

The Server Manager Administration page provides controls for executing server commands.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Options</th>
<th>Help</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Start the RAD-Series Server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Stop</td>
<td>Stop the RAD-Series Server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Restart</td>
<td>Restart the RAD-Series Server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Status</td>
<td>Status of the RAD-Series Server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Time</td>
<td>RAD-Series Server Time</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Message frame below the Administration page displays the most recently executed command and its result (server messages). Initially, this frame is empty.

Starting the Server

To start one or more RAD-Series Servers:

1. In the Server Status frame, select the server(s) to start. Be sure only these servers are selected.
2. In the Navigation frame, click Administration.
3. Click Start.

You’ll see the result of each RAD-Series Server start in the Message frame. There should be a next to the server(s) in the Server Status frame.
Setting Server Start Options

Use the Server Start Options page to assign non-default arguments for RAD-Series Server startup.

**Note:** These startup arguments are not part of the RAD-Series Server configuration files. They are stored locally on the Server Manager and apply to all RAD-Series Servers started by the Server Manager.

**UDP Ports**

You can change the default port the RAD-Series Server uses to listen for authentication or accounting requests from the UDP standard 1812 and 1813.

**Note:** The listen ports configured in any `radius_socket()` blocks override these default values.

The authentication and accounting relay ports are used when forwarding requests to machines using different port numbers than the standard 1812 and 1813.

**Debug Level**

The debug level specifies the amount of detail written to the `radius.debug` file. You can set the debug level to a value between 0 and 4. Each level includes the information in the levels before it. Higher levels write more information to the debug file, slowing performance. Debugging is intended for limited time use for testing purposes.

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No debugging (default)</td>
</tr>
<tr>
<td>1</td>
<td>Brief trace</td>
</tr>
<tr>
<td>2</td>
<td>High-level FSM output, some function tracing, A-V pairs, etc.</td>
</tr>
<tr>
<td>3</td>
<td>Full function tracing</td>
</tr>
<tr>
<td>4</td>
<td>Low-level FSM and configuration file output</td>
</tr>
</tbody>
</table>

**Reset Logs**

You can set the RAD-Series Server’s log file to be renamed to a file with the extension `.old` and to start with an empty log file each time the server is started. The debug file is always cleared on each startup. The server can also be configured to ignore reading the session table file (`session.las`) when the server is started.
To Change Server Start Options

1. In the Navigation frame, click Administration.

2. Click the button next to the Start button to display the Start Options page.

3. Make the desired changes.

4. Click OK.

Stopping the Server

To stop one or more RAD-Series Servers:

1. In the Server Status frame, select the RAD-Series Server(s) to stop. Be sure only these servers are selected.

2. In the Navigation frame, click Administration.

3. Click Stop.

You’ll see the results of each server stop in the Message frame. There should be a next to the server(s) name.

Restarting the Server

The Restart function causes selected RAD-Series Server(s) to reload a new configuration without first being stopped and restarted.

1. In the Server Status frame, select the RAD-Series Server(s) to restart. Be sure only the desired servers are selected.

2. In the Navigation frame, click Administration.

3. Click Restart.

You’ll see the results of each server restart in the Message frame.

You must stop and start the RAD-Series Server to apply all server startup options and the following server properties:

- Server Certificate Path
- Certificate Revocation List Path
- Server Private Key Path
• Client Certificate Authority Path
• Random Seed Path
• Hold Replies

You must stop and start the RAD-Series Server to re-read the following configuration files, which are not editable via the Server Manager:
• dictionary
• vendors
• radius.fsm
• log.config
Reporting Server Status

Use the Status function to check the operational status of the selected RAD-Series Server(s).

**Note:** To see extended output, a localhost entry in the server’s Access Devices or Proxies list is required.

1. In the Navigation frame, click Administration.
2. In the Status frame, select the RAD-Series Server(s) for which to report status.
3. Click Status.
   You’ll see the results of each status check in the Message frame.

Extended Server Status Output

The extended status message contains this additional information

<table>
<thead>
<tr>
<th>Example Message Lines</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Exit Codes</td>
<td>0 - Successful completion \texttt{-2} or \texttt{254} - Remote server had errors \texttt{-1} or \texttt{255} - Local errors \texttt{1} - Timeout errors</td>
</tr>
</tbody>
</table>
**Changing Status Command Options**

To change the values used in the Status command:

1. In the Status frame, select the RAD-Series Server.
2. In the Navigation frame, click Administration.
3. Click the button next to the Status button to display the Status Options page.
4. Change the:
   - Timeout (Seconds)
   - Number of Retries
5. Click OK.

**Reporting Server Time**

To check the system time on servers:

1. In the Status frame, select the RAD-Series Server(s).
2. In the Navigation frame, click Administration.
3. Click Time.
   You’ll see the results in the Message frame.
Load Configuration

This section shows how to load RAD-Series Server configurations into Server Manager for editing.

Loading copies configuration files from a source RAD-Series Server installation into the Server Manager workspace. You can download a configuration from any one server, edit it and save it to many servers.

Loading overwrites the temporary files in Server Manager’s workspace with the selected server’s active configuration files. If you do not save the previous set of configurations back to one of the connected servers, any work done in Server Manager is lost when you reload the configuration. If you start making changes and come back later, do not reload the configurations if you wish to continue configuring the same server. If you reload the configurations, then you will revert to the active server configuration and discard any unsaved changes.

The Server Manager only shows configurations for the last server loaded. When you wish to work with a different server, save the current configuration (if you wish to preserve it), then load the new server.

Loading does not copy any server security certificates or other security files. Manually copy these files between servers if they are to be shared.

Loading Configurations into Server Manager

To copy an RAD-Series Server configuration into the Server Manager temporary workspace:

1. In the Navigation frame, click Load Configurations.
2. In the Workspace frame, select the source server from which to copy.
3. Click the Load button. Wait until the transfer is confirmed.
Save Configuration

This section shows you how to:

- Save configurations after editing them in Server Manager
- Push configurations from one RAD-Series Server to another

Server Manager preserves changes to the temporary files between sessions, but you must save them to copy these changes to the RAD-Series Server’s actual configuration files. The changes will not take effect until you restart the server, so you can save changes any number of times without affecting the server operation.

You can save a configuration to any (or all) RAD-Series Servers that have an active connection with the Server Manager program. This way, you can reconfigure several servers at once or push configurations from a test machine to a production machine. The Save page always shows from which server the configuration originated and lets you select to which it should be saved.

**Note:** Server Manager saves the entire workspace configuration (access devices, proxies, local realms, users and RAD-Series Server properties) to the servers you select. It does not save server security certificates and other security files. You must manually copy these files between servers if they are to be shared.

**Note:** Saving a configuration to multiple servers will not work if specific local IP interfaces are configured. Such local specific IP interface parameters are listen sockets, default source proxying sockets, or source IP address.

**Saving Configurations**

1. In the Navigation frame, click Save Configurations.
2. In the Workspace frame, select the destination server(s). You can select as many as you wish.
3. Click the Save button. Wait until the transfer is confirmed.
Edit Configuration

This section contains instructions on using the Server Manager to configure the RAD-Series Server’s:

- Access devices — client devices sending Access-Requests and Accounting Requests to the server
- Proxies — other servers to which requests are forwarded and from which responses are received
- Authentication realms — user realms authenticated by this server
- User data stores — files, directories, and databases from which the server will retrieve user profiles

There are also procedures for setting up:

- The DHCPv4 Relay
- SNMP
- Server Properties

See “Using External Data Stores” on page 127 to configure the RAD-Series Server for use with an LDAP directory or other external data store.

Defining Access Devices

In Server Manager, an access device is any other network device—Network Access Server (NAS) or wireless Access Point (AP)— from which the RAD-Series Server will receive RADIUS service requests (aka its clients). It does not include servers we will proxy to or servers we will receive proxied requests from, which are configured separately under Proxies. The server configuration must include an entry for all the access devices that will communicate with the server.

These procedures modify the server’s clients file.

See “Defining Proxies” on page 45 for instructions on defining proxy servers.

Using Wildcards for IP Addresses

When specifying a client device name, you can use the Classless Inter-Domain Routing (CIDR) subnet notation to specify a set of contiguous IPv4 or IPv6 addresses. You can optionally use the *-style wildcard to replace any portion of the IPv4 address. For example, if a device name 15.0.0.0/8 is entered, then all clients in the ‘15.’ subnet can access the RAD-Series Server. If a device name 2001:3::/64 is entered, then any client with an IPv6 address in the range 2001:3::0-through-2001:3::ffff:ffff:ffff:ffff can access the RAD-Series Server. If a device name of ::/0 is entered, then any IPv6 client knowing the shared secret can access the RAD-Series Server or if a device name of * or 0.0.0.0/0 is entered, then any IPv4 client knowing the shared secret can
access the RAD-Series Server.

The following wildcard patterns are allowed, where \( h \) is a hexadecimal digit and \( w, x, y, \) or \( z \) are decimal numbers less than or equal to 255:

- \( 0::/0, \) \( 0000:0000::/0, \) \( 0000:0000:0000::/0, \) \( 0000:0000:0000:0000/0 \)
- \( hhhh::/16, hhhh:0000::/16, hhhh:0000:0000::/16, hhhh:0000:0000:0000/16 \)
- \( hhhh:hhhh::/32, hhhh:hhhh:0000::/32, hhhh:hhhh:0000:0000/32 \)
- \( hhhh:hhhh:hhhh::/48, hhhh:hhhh:hhhh:0000/48 \)
- \( 0.0.0.0/0, *, ***, **.*, **.*, **.*.*.* \)
- \( w.0.0.0/8, w.*, w.*.*, w.*.*.* \)
- \( w.x.0.0/16, w.x.*, w.x.*.* \)
- \( w.x.y.0/24, w.x.y.* \)

All of the entries on each of the above lines represent the same wildcard pattern, since they will match the same set of IP addresses.

No non-zero bits may follow the wildcard specification. The following are examples of invalid wildcards:

- \( 2003:24::/16 \)
- \( 2003::1/16 \)
- \( 15.24.*.42 \)

The more specific entries are given more precedence, when matching the source IP address of a request to a client entry. For example: \( 15.12.0.0/16 \) will have more precedence than \( 15.0.0.0/8 \) when matching a source IP address of, say, \( 15.12.1.2 \). The entries are internally arranged to make this precedence effective.

### Adding an Access Device

1. In the Navigation frame, click Access Devices.

2. Click the New Access Device link or ![plus](image).

3. In Name, enter the device’s IP address, a wildcard IP address or fully-qualified domain name.

4. Enter and confirm the Shared Secret to be used between this device and the RAD-Series Server.

   The secret must be less than 1023 characters and cannot contain spaces.

5. The Vendors field determines which vendor-specific attributes are returned to the client in RADIUS messages. Use CTRL + Click to select all that apply.

   Usually, it is sufficient to select the hardware vendor. If you don’t want to send any VSAs, choose Generic.
6 To define additional instructions for handling Access-Requests, check the Option boxes. These are advanced features that are not required normally.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>Dump packets into the server’s debug output file. To use this option, you must set the server’s debug level to &gt; 0 in Server Start Options.</td>
</tr>
<tr>
<td>No Encaps</td>
<td>Do not encapsulate vendor response. This option is useful if the client requires nonencapsulated A-V pairs.</td>
</tr>
<tr>
<td>Old CHAP</td>
<td>Use pre-RFC CHAP with this client.</td>
</tr>
</tbody>
</table>

7 Click Create.
Modifying a Device Definition
To change settings for an existing device:
1. In the Navigation frame, click Access Devices.
2. Click the device name link on the Access Devices page.
3. Change the settings.
4. Click Modify.

Deleting a Device
To completely remove a device from the RAD-Series Server’s list of clients:
1. In the Navigation frame, click Access Devices.

2. Click the x next to the device name on the Access Devices page.
3. Click Delete.
Defining Proxies

To proxy authentication or accounting requests with the RAD-Series Server, identify both:

- Proxy servers that this server may receive requests from
- Remote servers that this server may proxy requests to

Self-referring Client Entry (localhost)

If the RAD-Series Server has a self-referring client entry named localhost, the server Status command program (radcheck) will return extended information, such as authentication and accounting request statistics. This entry is automatically made in the Proxies list when the server is installed. Deleting it will change the Status command output to a single line, “host is|is not responding,” but won’t alter server functioning. See “Reporting Server Status” on page 36 for a description of the extended output.

Note: The localhost entry shown in the Proxies list should not be confused with the loopback localhost that appears in the Server Status frame and corresponds to an RAD-Series Server installed on the same host machine as the Server Manager.

Using Wildcards For Realms

When specifying a proxy realm name, you can use the wildcard syntax, *.realm.

This syntax provides a shorthand for handling several realms the same way. For example, a company may have several branches, eastern.company.com, western.company.com, and central.company.com. Using the wildcard *.company.com, all three realms would be forwarded to the same server.

It does not matter in what order you enter regular or wildcard realm names in the Server Manager. When the RAD-Series Server reads the realms it sorts the entries so that:

- Non-wildcard entries come first
- Wildcard entries of length $n$ come before wildcard entries of $< n$.

This ensures that wildcard entries are used only when there is no exact match among the regular entries and that when there are several wildcards that may apply, the “best-fit” entry is selected.
Receiving Requests from a Proxy Server

To define proxy servers from which the RAD-Series Server will receive authentication requests:

1. In the Navigation frame, click Proxies.
2. Click the New Proxy link.
3. In Name, enter the IP address, a wildcard IP address or fully-qualified domain name of the proxy server.
4. In Shared Secret, enter the string used to establish trust between the proxy server and the RAD-Series Server.
   The shared secret cannot be more than 1023 characters long or contain spaces.
5. The Vendors field determines which vendor-specific attributes are forwarded to the server in RADIUS messages. Use CTRL + Click to select all that apply.
   Usually, it is sufficient to select the hardware vendor. If you don’t want to send any VSAs, choose Generic.
6. Check the Advanced options to define any additional instructions for handling RADIUS messages. Unless you have special requirements, you probably do not need any options.
   Options are:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>Dump packets into the server’s debug output file. To use this option, you must set the server’s debug level &gt; 0 in Server Start Options.</td>
</tr>
<tr>
<td>No Append</td>
<td>If checked, the proxy server expects that all attributes which were sent in a transmitted Access-Request will be echoed in the received response. If unchecked the proxy server expects that all new attributes added to the response will follow the proxy server’s Proxy-State attribute.</td>
</tr>
<tr>
<td>Prune</td>
<td>Forces pruning as if the response were being returned to an access device. Using Prune with the Generic vendor option prunes all vendor-specific attributes before a message is returned to the proxy server.</td>
</tr>
</tbody>
</table>
7. Click Create.
Proxying Requests to a Remote Server

All the information needed for this can be configured using the Server Manager. To configure the RAD-Series Server as a proxy to a remote server:

1. In the Navigation frame, click Proxies.
2. Click the New Proxy link.
3. In Name, enter the IP address or fully-qualified domain name of the remote server.
4. In Shared Secret, enter the string used to establish trust between the remote server and the RAD-Series Server.
   The shared secret cannot be more than 1023 characters long or contain spaces.
5. The Vendors field determines which vendor-specific attributes are to be forwarded to the remote server in request messages. Generally you would select Generic, but you can choose a set that applies if there are special requirements.
   Use CTRL + Click to select more than one.
6. Enter all the Realms to forward to the remote server:
   • Choose Add New Realm from the drop-down menu.
   • On the Proxy Realm dialog, enter the realm Name.
   • To Forward Accounting as well as authentication requests, click the Yes option button.
   • Click Save.
   Repeat this step for each realm to be proxied.
7. To forward requests from a specified source IP address, enter the IP address in the Source IP Address field. This value will override the Default Local IP Address for Proxy Socket parameter.
8. To forward requests from a specified port, enter the port number in the Source Port field. If not specified, the server will choose an ephemeral port number.
9. To send authentication requests to a port other than the RAD-Series Server’s default, enter the port number in Authentication Relay Port.
   This number overrides any relay port you set up under the RAD-Series Server’s start options, the content of /etc/services, or the RAD-Series Server’s default of 1812.

Note: The current RADIUS default ports are 1812 and 1813. Older RADIUS servers may listen for requests on ports 1645 and 1646.

10. To send accounting requests to a port other than the RAD-Series Server’s default, enter the port number in Accounting Relay Port.
    This number overrides any relay port you set up under the RAD-Series Server’s start options, the content of /etc/services, or the RAD-Series Server’s default of 1813.
11. Click Create.
Modifying a Proxy Configuration

To change the settings for any proxy relationship between the RAD-Series Server and another server:

1. In the Navigation frame, click Proxies.
2. Select the other server from the Proxies list.
3. Change the settings as necessary.
   - To stop proxying a realm:
     • Select the realm from the Realms to Forward drop-down menu.
     • Click Delete.
   - To change ports: enter the new Authentication Relay Port or Accounting Relay Port number.
   - To stop forwarding accounting messages:
     • Select the realm from the Realms to Forward drop-down menu.
     • Change the Forward Accounting selection to Yes or No.
4. Click Modify.

Deleting a Proxy Configuration

To completely stop receiving requests from or forwarding requests to a remote server:

1. In the Navigation frame, click Proxies.
2. Click the button next to the server name the Proxies list.
3. Click Delete.
Proxying Accounting Requests to a Central Server

By modifying the Finite State Machine table (.fsm), you can forward all received accounting messages to a central server. This configuration will disable all local accounting for all realms normally handled by the RAD-Series Server.

To forward accounting for a single realm, follow the steps in “Proxying Requests to a Remote Server” on page 47.

To proxy all accounting:

1. Complete the steps to add the server to your Proxies list.

2. In a text editor, open radius.fsm (by default in etc/opt/aaa/) and locate the lines:
   
   ```
   AcctWait:
   *.ACK            ACCT_SWITCH           AcctLog
   *.ACCT_DUP       ACK                  ReplyHold
   ```

   Replace them with:
   
   ```
   ACCTwait:
   *.ACK            RAD2RAD               ReplyHold    Xstring="central.server"
   *.ACCT_DUP       RAD2RAD               ReplyHold    Xstring="central.server"
   ```

   where “central.server” is the fully-qualified domain name or IP address of the central accounting server which must be found in the clients file.

3. To forward the accounting to a port other than the RAD-Series Server’s default, modify the clients file for that port, see “Proxying Requests to a Remote Server” on page 47.

4. Save and close radius.fsm.

5. Stop and start the server.
Defining Realms

Generally, a realm is a group of users who share a common characteristic, such as being employees of the same company, division, department, or subscribers to the same internet service. All users of a given realm are:

- Stored in the same location
- Authenticated by the same protocol
- Identified by their User-Name attribute value (e.g.: userid@realm)

Define a separate realm for each group of users who:

- Use different authentication protocols
- Use different domain names
- Are stored in different locations (different directories or files)

You may also need multiple realms if using two-phase EAP methods, such as TTLS. For more information on configuring RAD-Series Servers for WLAN and 802.1X environments, use the Secure LAN Advisor from the Server Manager Navigation frame.

These procedures modify the RAD-Series Server’s authfile and EAP.authfile.

About Realms

Realm vs. Domain

A domain refers to a fully-qualified domain name registered with DNS. The realm name may or may not be a domain name. For example, the NULL realm exists to accommodate users who are not associated with any domain name, but who still require authentication.

In general, we recommend that if users in a realm are required to supply a domain name upon login, the domain name be used as the realm name—for example, yourcompany.com. Similarly, any flat file used to store user profiles for this realm should also bear the realm name.

NULL Realm

The NULL realm is defined in the default RAD-Series Server configuration. This is beneficial to those people who manually edit the las.conf file to add the NULL realm and store the users in the default users file.

The NULL realm can be reconfigured to handle authentication requests where the user doesn’t supply a domain name, such as for Windows domains. Any time a user name does not contain the realm portion of the NAI format userid@realm, the server automatically considers the user part of the NULL realm and applies the authentication method defined for NULL.

The default users file, found in fresh installations of the server, is used for testing the server installation and is set to perform password authentication on the default test_user. Remove this user from the file when you are done testing the initial installation.
There can be only one NULL realm per server. However it can exist once with each of the possible protocol options.

**Wildcards**

The wildcard * can be used in authentication realm names, as well as for proxy realms. See “Using Wildcards For Realms” on page 45 for more information.

**Configuring TTLS Authentication**

If you are using TTLS to authenticate users, you will need to define at least two realms for the group:

- One realm to establish the tunnel to the outer realm user (e.g.: anonymous@tunnelrealm.com)
- Inner authentication realms that indicate where user profiles are stored and the authentication method that will be used to authenticate actual users

When defining a TTLS tunnel realm, the name must match what has been configured on the client device as the anonymous user’s realm name. Usually, this is the primary domain for the organization. When defining the inner authentication realms, the name should be the group’s own logon domain name or else use the NULL realm.

TTLS can be used to authenticate users on legacy RADIUS servers, once the tunnel has been established to secure the connection between the user and the RAD-Series Server.

The process for configuring TTLS realms is:

1. Configure your TTLS clients, so you know the realm of the anonymous user.
2. Add a tunnel realm.
3. Either:
   - Add authentication realm(s) for the inner users.
   - Configure the RAD-Series Server as a proxy to the legacy server where users will be authenticated. See “Proxying Requests to a Remote Server” on page 47.
4. Generate and install server-side certificates and keys. See “Administering Digital Certificates” on page 60.

**Add a Tunnel Realm**

To add a TTLS tunnel realm:

1. In the Navigation frame, click Local Realms.
2. Click the New Local Realm link or .
3. In Name, enter the anonymous user’s realm name as set up on the user machines.
4 In Realm Type, choose TTLS Tunnel.
5 Click Create.

Add Authentication Realms

Follow the steps in “Defining Authentication Realms” on page 54 to add the authentication realm.
- In Realm Type, choose Authentication.
- For TTLS with PAP or CHAP, select Password Authentication for the Security Method.
- For TTLS with EAP, select EAP Authentication for the Security Method, then choose all the methods set up on your clients from the drop-down list. Use CTRL + Click to select more than one.

Configuring PEAP Authentication

PEAP implementations use the same realm name for the outer and inner user, even though it is a two-phase authentication method. You need only one authentication realm for each domain name.

You cannot authenticate users on a legacy RADIUS server with PEAP.

The process for configuring PEAP realms is:
1 Configure your PEAP clients.
2 Add authentication realm(s) for the inner users.
3 Generate and install server-side certificates and keys. See “Administering Digital Certificates” on page 60.

Add Authentication Realm

Follow the steps in “Defining Authentication Realms” on page 54 to add the authentication realm.
- In Realm Type, choose Authentication.
- For the Security Method, choose EAP Authentication, then select the all the PEAP methods set up on your clients from the drop-down list. If you are using any third party supplicants that do not support PEAP version 1, you will need to select “PEAP Version 1 Disabled”.

Note: PEAP client software is installed with Windows® XP Service Pack 1 (or later), Windows® Vista, Windows® 7, and third-party supplicants.
Configuring TLS Authentication

TLS does not access a data store for user profiles. Instead, this method requires certificates to be installed on both the RAD-Series Server and on each user workstation.

The process for configuring TLS realms is:

1 Add authentication realm(s).
2 Generate and install server and client-side certificates. See “Administering Digital Certificates” on page 60.
   • For the server, you will need two certificates: a CA (certificate authority) certificate and a server-specific certificate.
   • For each user workstation, you will need the same CA certificate and a client-specific certificate. Client certificates must have the User-Name in the field that was selected in Server Properties > Certificate Properties > Client User Name Attribute. See “Client User Name Attribute” on page 73.

Add Authentication Realm(s)

Follow the steps in “Defining Authentication Realms” on page 54 to add the authentication realm.
• In Realm Type, choose Authentication.
• In User Profile Storage, choose No Store - EAP TLS Certificates.
Defining Authentication Realms

Follow these steps to define each user realm to be authenticated by the RAD-Series Server.

See the Secure LAN Advisor (found in the Navigation frame) for more detailed information on configuring RAD-Series Servers for WLAN and 802.1X environments.

1. In the Navigation frame, click Local Realms.

2. Click the New Local Realm link or .

3. In Name, enter the domain name users enter at login.

4. In Realm Type, choose Authentication.

5. In User Profile Storage, choose the type of data store you’re using for this realm.
   - LDAP — LDAP directory
   - Local Storage — flat file identified by name in User Storage Parameters
   - No Store - TLS — authenticate using client and server security certificates, rather than user profiles
   - No Store - Allow — no authentication, allow all users in this realm
   - No Store - Deny — no authentication, deny all users in this realm
   - Oracle — Oracle database. Requires special licensing option.
   - OS Security Database — UNIX password storage
   - SecurID/ACE server — RSA SecurID identification and authentication. Requires special licensing option.
   - KTH Kerberos IV — authenticate against a KTH Kerberos version IV server. Requires special licensing option.
   - CNS Kerberos IV — authenticate against a CNS Kerberos version IV server. Requires special licensing option.

6. Enter any additional User Storage Parameters that appear:
   - LDAP — complete steps in “Identifying LDAP Directories” on page 55
   - Local Storage — enter unique realm file name or select the default users file
   - Oracle — complete steps in “Identifying Oracle Servers” on page 58

7. Select the Security Method:
   - For PAP, CHAP, or MS-CHAP, choose Password Authentication.
   - For all other 802.1X methods, select EAP Authentication, then choose all the methods set up on your clients from the drop-down list.

   Use CTRL + Click to select more than one option.

   You can use the authfile to manually define custom authentication types. See “Authfile Entry Syntax” on page 222 for instructions.

8. To define a packet filter for the realm, enter the filter name in Filter ID.

   This will override any explicit filters defined in user profiles.
9 To limit concurrent sessions, click Yes to enable Session Tracking.

**Note:** Enabling Session Tracking sets the number of individual concurrent sessions to the global Simultaneous Use value set in Session Properties under the Server Properties page. You can override this number by defining a Simultaneous-Use value for an individual user in the user profile.

10 Click Create.

**Identifying LDAP Directories**

When you choose LDAP from the User Profile Storage drop-down list on the Add a Realm page, a set of additional parameters appears under User Storage Parameters. These fields let you identify the LDAP directories from which the RAD-Series Server will retrieve user profiles.

1 To treat *userid* as binary, case-sensitive, choose **BIN** for the **Filter-Type**. To treat *userid* as case-insensitive, choose **CIS** for the **Filter-Type**.

2 To search the LDAP Directory based on an attribute from the request other than the default one, *User-Id*, change the **Request-Attribute-For-Search** field to the desired attribute name.

3 From the drop-down list that appears in User Profile Storage Parameters, choose New LDAP Directory.

4 On the LDAP Directory dialog, enter the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directory Name</td>
<td>Name of the directory that appears in the Server Manager drop-down list. This does not have to be the actual directory name, just an identifier.</td>
</tr>
<tr>
<td>Host</td>
<td>IPv4 or IPv6 address or fully-qualified domain name of the host the LDAP directory runs on.</td>
</tr>
<tr>
<td>Port</td>
<td>TCP port number the LDAP directory runs on. If no value is given, defaults to either 389 for non-SSL or 636 for SSL ports.</td>
</tr>
<tr>
<td>Use SSL</td>
<td>Enable (Yes) or disable (No) SSL between the RAD-Series Server and this LDAP directory. If using SSL, also specify the server’s CA certificate path and file in the &quot;ProLDAP Properties&quot; on page 78.</td>
</tr>
<tr>
<td>Administrator</td>
<td><em>Distinguished Name (dn)</em> of the administrative user permitted to search the LDAP directory. This ID should match the ID you set up on your directory for the RAD-Series Server. This user must have read access to all the users to be authenticated by the RAD-Series Server and their passwords. If this field is omitted, the server will perform a bind to the directory using the user credentials from the Access-Request if it is necessary to validate the user’s password.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Password / Confirm Password</td>
<td>Password used by the Administrator to bind to the LDAP directory server. Enter it twice to confirm it.</td>
</tr>
<tr>
<td>Search Base</td>
<td>Pointer into the directory where the RAD-Series Server will begin to search for users in this realm. Enter a comma-delimited list of attribute-value pairs that represent the directory levels, no spaces. There is no default value.</td>
</tr>
<tr>
<td>Filter</td>
<td>Filter specifies which LDAP attribute to use in the lookup. The three values are User-Id, UID and sAMAccountName. User-ID is case sensitive in LDAP and UID is case insensitive in LDAP. sAMAccountName MUST be used when accessing Active Directory via its LDAP interface. The default value is UID.</td>
</tr>
<tr>
<td>Access Mode</td>
<td>Determines the mode to be used to access this LDAP server for this LDAP directory. There are three mode: Bind, Search and Auto. The default Access Mode is Auto.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Bind</strong> When binding as the user for authentication is desired. No Policy-Pointers, check items, or reply items will be returned to the RAD-Series Server when <strong>Bind</strong> is specified.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Search</strong> When a LDAP search as the configured administrator is desired. The RAD-Series Server expects the user's password in the search result. The RAD-Series Server must perform an administrator search on the LDAP server when Policy-Pointers, check items, or reply items must be returned.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Auto</strong> When a LDAP search as the configured administrator (search anonymously if no configured administrator) is desired. After the search the RAD-Series Server expects the password to be returned in the search results. The RAD-Series Server binds as the user if the password is not available. Policy-Pointers, check items, and deny items will not be returned by the LDAP server if the RAD-Series Server reverts to bind. This mode can affect performance, since two LDAP operations may occur for one authentication.</td>
</tr>
<tr>
<td></td>
<td>IMPORTANT: You must use <strong>Auto</strong> with a Microsoft Active Directory.</td>
</tr>
</tbody>
</table>

5 Click Save.

6 To associate other LDAP directories with this realm, repeat Steps 3 through 5.

Each realm may be configured with up-to-four redundant LDAP directories, which are used by the RAD-Series Server when it performs load balancing and failover.

7 Complete the procedure to add or modify the realm.
Modify a Directory Configuration

To change the information entered for any of the defined LDAP directories:

1. Click Local Realms, then click the button next to the realm name to display the Modify Realm page.
2. Select the directory from the User Storage Parameters drop-down list.
3. On the LDAP Directory dialog, make the necessary changes.
4. Click Save.
5. Click Modify.

Delete a Directory

1. Click Local Realms, then click the button next to the realm name to display the Modify Realm page.
2. Select the directory from the User Storage Parameters drop-down list.
4. Click Modify.
Identifying Oracle Servers

When you choose Oracle from the User Profile Storage drop-down list on the Server Manager Add a Realm page, a set of additional parameters appears under User Storage Parameters. These fields let you identify the Oracle daemon (db_srv) that will retrieve user profiles for the RAD-Series Server.

1. From the drop-down list that appears in User Profile Storage Parameters, choose New Oracle Server.
2. On the Oracle Server dialog, enter the following fields. All are required:
   - **Database Name**: Name for this Oracle database to appear in the User Storage list. Does not have to be the database name in Oracle.
   - **Host**: IPv4 address or fully-qualified domain name of the db_srv daemon host machine.
   - **Port**: TCP port number the db_srv daemon uses for authentication messages.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>Name for this Oracle database to appear in the User Storage list. Does not have to be the database name in Oracle.</td>
</tr>
<tr>
<td>Host</td>
<td>IPv4 address or fully-qualified domain name of the db_srv daemon host machine.</td>
</tr>
<tr>
<td>Port</td>
<td>TCP port number the db_srv daemon uses for authentication messages.</td>
</tr>
</tbody>
</table>

Each listed server must have a unique host name and port (you cannot have two servers running on the same machine and listening to the same port number).

3. Click Save.
4. To associate other Oracle servers with this realm, repeat Steps 2 through 4.
   - Each realm may be configured with up-to-32 redundant Oracle servers, which are used by the RAD-Series Server when it performs load balancing and failover.

5. Complete the procedure to add or modify the realm.

Modify an Oracle Server Configuration

To change the information entered for any of the defined Oracle servers:

1. Click Local Realms, then click the button next to the realm name to display the Modify Realm page.
2. Select the server from the User Storage Parameters drop-down list.
3. On the Oracle Server dialog, make the necessary changes.
4. Click Save.
5. Click Modify.
Delete an Oracle Server

1 Click Local Realms, then click the button next to the realm name to display the Modify Realm page.
2 Select the server from the User Storage Parameters drop-down list.
3 On the Oracle Server dialog, click Delete.
4 Click Modify.

Modifying a Realm Definition

To change settings for an existing authentication realm:
1 In the Navigation frame, click Local Realms.
2 Click the realm name link on the Local Realms page.
3 Change the settings.
4 Click Modify.

Deleting a Realm

To completely remove an authentication realm:
1 In the Navigation frame, click Local Realms.
2 Click the next to the device name on the Local Realms page.
3 Click Delete.
Administering Digital Certificates

TLS, TTLS, and PEAP use certificates for authentication. To configure realms using these methods you must:

- Generate certificates and the corresponding private keys for the RADIUS server.
- Install signed certificates and private keys in the RAD-Series Server’s directories.
- For TLS, you must also generate certificates and private keys for each user workstation that will access the network.

If you are supporting multiple realms, configure digital certificates after you’ve added all of your realms.

You can deploy digital certificates in an environment with supporting infrastructure—for example, an organization with a PKI and user-specific certificates.
Using the “Self-Signed” Digital Certificates

The RAD-Series Server is installed with a sample set of self-signed” digital certificates. Server Manager uses these certificates by default. You can use the self-signed certificates in test environments for TLS, TTLS and PEAP.

The self-signed server certificates are in /etc/opt/aaa/security/. They are:

- rsa_cert.pem — server certificate
- rsa_key.pem — server key
- ca_list.pem — list of client CA certificates
- sampleclientcert.p12 — sample client certificate

For TTLS and PEAP

If you are using TTLS or PEAP, the default certificates are safe to deploy in your production environment. The RAD-Series Server is its own Certificate Authority. If you are managing multiple RAD-Series Servers, you must have the same set of digital certificates on each server in your configuration. Pick one of your RAD-Series Servers and copy the set of self-signed digital certificates to every RAD-Series Server in the configuration. You should save each RAD-Series Server's original self-signed certificates for future use.

For TLS

If you are using TLS, use the default certificates to simulate and troubleshoot TLS certificate administration before you deploy your own enterprise certificates.

1. Copy /etc/opt/aaa/security/sampleclientcert.p12 to the user’s PC and add it to the certificate storage of the supplicant:
   - The pass phrase is blank for sampleclientcert.p12
   - The user name for sampleclientcert.p12 is: sampleclient@samplecompany.com

2. Configure a TLS realm for eap.realm on the RAD-Series Server
Using Your Own Digital Certificates and Keys

If you don’t use the default self-signed RAD-Series Server certificates, you must generate certificates and the corresponding private keys for the RADIUS server and (when using TLS) each workstation that will access your network services. To acquire a server- or client-specific certificate, submit a certificate signature request (CSR) to a certificate authority (CA), such as VeriSign or Microsoft.

**Note:** For TLS, the same Certificate Authority must be used to sign certificates for both the RAD-Series Server and the user workstation.

Obtaining Certificates and Creating Keys

Follow these steps to create a CSR and corresponding key:

1. Start the RAD-Series Server that will be authenticating access requests.
2. Create or choose a directory for the certificates and your private key. Because the private key is stored unencrypted, it is very important to restrict access to the directory.
3. Use the OpenSSL Certificate Request Generator or another utility to create two files:
   - the key, rsa_key.pem
   - the CSR, rsa_cert.pem

   To create these files with openssl, enter the following at the command line prompt:
   
   ```bash
   openssl req -new -nodes -out req.pem -keyout Key-location
   
   For Key-location specify the rsa_key.pem file, including the path of the directory you have chosen to store the server- or client-specific key. For example: /etc/opt/aaa/security/rsa_key.pem.

   **Note:** Do not protect the key with a passphrase.

4. You will be prompted to enter information that will be used to generate the private key file and CSR file. Complete the information according to the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Enter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Country code</td>
<td>Two-letter ISO code for your country. The code for the United States is US.</td>
</tr>
<tr>
<td>Organizational unit name</td>
<td>Name of the division, department, or other organizational unit that will be authenticated using this certificate.</td>
</tr>
<tr>
<td>Organization name</td>
<td>Name of your organization. Verisign may require any host names to belong to a domain registered to this organization.</td>
</tr>
<tr>
<td>E-mail address</td>
<td>The e-mail address that should be used to receive the certificate.</td>
</tr>
</tbody>
</table>
5 Submit the CSR to VeriSign or another certificate authority. Request the certificate in Base-64 format.

You will receive the server- or client-specific certificate through the e-mail address you specified when you used openssl to generate the CSR or the certificate may be downloaded from a web page.

How the certificate is submitted and delivered varies according to the certificate authority that you use. For example, a CSR is submitted to Microsoft and the certificate is downloaded from a web page.

### Installing Server Certificates and Keys

1 Add the CA certificate to the `ca_list.pem` file (found in `/etc/opt/aaa/security/` by default) by copying and pasting the contents of the certificate.

2 Copy the files for the server-specific certificate and key contents into the RAD-Series Server security directory (`/etc/opt/aaa/security/` by default).

### Installing Client Certificates and Keys

For each user workstation where you will make a TLS connection:

1 Install the CA certificate in the Trusted Root Certification Authorities store.

2 Install its user-specific (or computer-specific) key and certificate:
   - Install computer-specific certificates in the Local Computer certificate store. Set the Subject Alternative Name property to match the FQDN of the wireless client computer account, which should be the same as the User-Name (userid@realm).
   - Install user-specific certificates in the Current User certificate store. Set the Subject Alternative Name property to match the universal principal name (UPN) or common name of the user account, which should be the same as the User-Name (userid@realm).
Defining Digital Certificate Locations

The RAD-Series Server uses the default self-signed certificates by default. If you want to use your own certificates, you must define where the required certificates reside on the server.

1. Click Server Properties in the Navigation Tree.
2. Click Certificate Path Properties in the Main Screen.
3. Click each of the following links in the Workspace area, then enter the full path and click Create:
   - Certificate Path: For TLS, TTLS, and PEAP. Full path to the RAD-Series Server certificate in .pem or .cer format.
   - Private Key Path: Full path to the file in .pem or .cer format that contains the private key used to generate the RAD-Series Server certificate. This file cannot be encrypted.
   - Certificate Authority Path: For TLS, TTLS, and PEAP. Full path to the CA certificate for the client certificate. Used by the RAD-Series Server to authenticate client certificates. The CA certificate for the client certificate must be in .pem format.
   - Random Seed Path: For TLS, TTLS, and PEAP. Full path to the random seed used to generate keys.
Defining Users

User profiles may be stored locally (in realm flat files or the default users file) or in an external source, like an LDAP directory. Use the procedures in this section to add users to realm files for local storage. Otherwise, use the interface to your data repository to add user profiles. If you have a small number of users from different realms, you can store all of their profiles in the default users file.

The following procedures modify the realm file you specified when configuring the realm.

For information on using LDAP storage, see “Using External Data Stores” on page 127.

User A-V Pairs

User profile information is stored as a set of A-V pairs. These A-V pairs mostly fall into two primary groups:

- Check/deny items--for authorization (simple policy). This includes checking for Service Type, NAS/Login ID, Caller/Calling Station ID, etc.
- Reply items--for provisioning. This includes any session data returned to the access device, such as session control limits, filters, callback numbers, IP addresses, port limits, and reply messages.

The Server Manager creates standard RADIUS A-V pairs based on your selections and writes them in the realm file user entry. Some information, such as vendor-specific attributes, are entered on the Add User page Free tab using A-V pair syntax. All user A-V pairs, whether entered through the Server Manager GUI or directly into the file, represent a one-to-one match between the attribute and a specified value. You cannot specify lists of values for any single user attribute.

Note: Wireless access points that adhere to the 802.1X standard should support the reply item attributes utilized by Server Manager. Verify the capabilities of your access points with the access point vendor.

See “Configuration Files” on page 192 for user A-V pair syntax and a description of Interlink-specific user attributes. Standard RADIUS attributes are defined in the RAD-Series Server’s dictionary file, by default in /etc/opt/aaa.

User Name Formats

A user name in Network Access Identifier (NAI) format should look like userid@realm, for example: “you@yourcompany.com.” When adding users to local realm files, supply only the userid part of their NAI format login string.
**Adding User Profiles**

To add new users to a realm file:

1. In the Navigation frame, click Local Realms for users stored in a realm file or click Users for users stored in the default users file.

2. If you clicked Local Realms then click the button next to the realm name.

3. Enter the User Name and click Create.

**Note:** User Name must be less than 254 characters and can contain only the letters A-Z and a-z, numbers 0-9, dots '.', , dashes '-', underscores '_', and '!' and '$'.

4. Complete the authentication information on the General tab:
   - Enter a Password and Confirm Password. The password cannot contain the \ character.
   - To store passwords in hashed form, choose a Password Hashing Mechanism compatible with the user’s authentication method.

**Note:** For PEAP, and TTLS, choose a password hashing mechanism compatible with the inner realm authentication method.

<table>
<thead>
<tr>
<th>Authentication Method</th>
<th>Hashing Mechanisms</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAP</td>
<td>Any</td>
</tr>
<tr>
<td>MS-CHAP</td>
<td>Plain Text or NT Hash</td>
</tr>
<tr>
<td>EAP-GTC</td>
<td>Any</td>
</tr>
<tr>
<td>EAP-MD5</td>
<td>Plain Text or MD5 Hash</td>
</tr>
<tr>
<td>EAP-TLS</td>
<td>none</td>
</tr>
</tbody>
</table>

5. If you do not need to specify any other information for this user, click Create again. Otherwise, follow the procedures in “Controlling and Provisioning Sessions” on page 67 to complete the user profile form, then click Create.
**Controlling and Provisioning Sessions**

Complete the Server Manager Users page tabs to enter provisioning information, such as:

- Filters
- Session limits
- Point of access

Session control attributes appear as check, deny, or reply items in the realm file.

**Specify Login Service Type**

To configure users for login service types (such as dumb-terminal access):

1. Complete the steps to add a new user.
2. On the General tab, choose Login from Service Type drop-down menu.
3. Click the NAS/Login tab and complete the relevant Login fields.

**Specify Framed Service Type**

To configure dial-up users for framed service types:

1. Complete the steps to add a new user.
2. On the General tab, choose Framed from Service Type drop-down menu.
3. Click the Framed tab and select the Framed Protocol to use.
4. Optionally, complete any of the other Framed fields.

**Set Timeout Values**

1. Complete the steps to add a new user.
2. On the General tab, enter:
   - Session Timeout — how many consecutive seconds user can access the service.
   - Idle Timeout — how many consecutive seconds of idle connection time can pass before the session is terminated.

   **Note:** The RAD-Series Server does not enforce either timer, it just sends them to the NAS for it to use.

**Establish Filters**

If you’ve defined filters on your access devices, you can specify which filter to apply to the user. You can only associate one filter with the user.

1. Complete the steps to add a new user.
2 On the General tab, enter the filter name exactly as set up on your device in Filter ID.

**Establish Callback Number**

If you’re setting up a callback service type.

1 Complete the steps to add a new user.

2 On the General tab, choose one of the Callback Service Type(s) from the drop-down menu.

2 Enter either:
   - Callback Number to dial exactly this string of numbers
   - Callback ID name of a place and number to be interpreted by the access device.

**Control Access by Device**

To limit users to access only through specific devices:

1 Complete the steps to add a new user.

2 Click the NAS/Login tab and enter the NAS IP address.

3 Optionally, enter:
   - NAS Port — port number that must appear in an Access-Request for authorization to succeed
   - NAS ID — NAS identifier that must appear in an Access-Request for authorization to succeed
   - NAS Port Type — if NAS differentiates among its ports

**Assign a Static IPv4 Address**

1 Complete the steps to add a new user.

2 Click the Framed tab and enter the IPv4 address in Framed IP Address.

3 If the user is a router to a network, also enter the Framed IP Netmask.

**Define DHCP IPv4 Address Pool**

Use this to associate an address pool with the user if you’re using the RAD-Series Server as a DHCPv4 relay. Be sure to also enable DHCP in Server Properties. See “Using DHCP” on page 84.

1 Complete the steps to add a new user.

2 Click the Free tab and enter the A-V pair: Address-Pool=name-of-pool.
Control Access by Dial-Up Number/MAC Address

This configuration limits the user to calling from or to the specified dial-up number or, in the case of a wireless network, to the station’s MAC address.

To deny access to specific numbers/addresses, such as 800 numbers, see “Deny Access” on page 70.

1. Complete the steps to add a new user.
2. Click the Others tab.
3. To allow the user to only call from a specific phone number or machine, enter the number or MAC address in the Calling ID field.
   - To allow the user to only call to a specific phone number or access point, enter the number or MAC address in the Called ID field.

Set Reauthentication Session Timeout

For wireless users, you can set how often (in seconds) the access point will attempt to reauthenticate the user. If authentication fails, the access point terminates the session.

To do this procedure you must enable Session Tracking for the user’s realm. See “Defining Authentication Realms” on page 54.

**Note:** Some access points do not properly support session tracking with RADIUS accounting messages.

1. Complete the steps to add a new user.
2. Click the Free tab and in Reply text enter:
   - Terminate = 1
3. In Check text, enter:
   - Session-Timeout = Number of seconds

Override Concurrent Session Limit

To do this procedure you must enable Session Tracking for the user’s realm. See “Defining Authentication Realms” on page 54.

**Note:** Enabling Session Tracking sets the number of individual concurrent sessions to the global Simultaneous Use value set in Session Properties under the Server Properties page. You can override this number by defining a Simultaneous-Use value for an individual user in the user profile sessions (zero denies all sessions for the user, while -1 imposes no session limits).

1. Complete the steps to add a new user.
2. Click the Free tab and in Check text enter:
   - Simultaneous-Use = Max-number-sessions
**Set Port Limit**

If you’re using Multilink PPP, you can set the maximum number of ports that may be assigned to the user for a single session.

1. Complete the steps to add a new user.
2. Click the Others tab and in Port Limit enter the maximum number of ports.

**Deny Access**

To deny a user access through a specific connection point:

1. Complete the steps to add a new user.
2. Click the Free tab and in Check text enter any or all of the following:
   - NAS-Port != Port-number
   - NAS-Identifier != value
   - Calling-Station-ID != AP-MAC-address
   - Called-Station-ID != dial-up number

**NOTE:** Spaces before and after the “!=” are required.

**Policy-Pointer**

Advanced policy can be used apply special criteria for deciding if the user should be allowed in or which reply items to return. It can be invoked by defining the `policy-pointer` attribute with the decision file name as its value. See “User/Realm policy” on page 143 for information on using this attribute.

1. Complete the steps to add a new user.
2. Click the Free tab and in Check text enter the following:
   - `Policy-Pointer = file.name`
Modifying a User Profile

1. In the Navigation frame, click Local Realms for users stored in a realm file or click Users for users stored in the default users file.

2. If you clicked Local Realms then click the button next to the realm name.

3. Click the button next to the User Name.
   If you don’t see the user listed, enter the User Name at the top of the page and click Search.

4. Change the entries on any of the five User tabs.

Note: To change the password hashing mechanism, first reenter and confirm the password.

5. Click Modify.

Deleting Users from Realm Files

To remove a user profile from the realm file:

1. In the Navigation frame, click Local Realms for users stored in a realm file or click Users for users stored in the default users file.

2. If you clicked Local Realms then click the button next to the realm name.

3. Click the button next to the user name on the User page.

4. Click Delete.
Defining Server Properties

Use the Server Properties page to change the default RAD-Series Server settings.

These procedures modify the RAD-Series Server’s `aaa.config` and/or `las.conf` files.

Some parameters/features cannot be handled via the Server Manager. For example if the Tokenpool parameter is needed then the `las.conf` file must be manually edited.

Modifying Server Properties

1. In the Navigation frame, click Server Properties.
2. Click the link to the group of properties you wish to modify.
3. Change the values.
4. Click Modify.

See the topics below for a list of configurable properties.

Certificate Properties

These properties specify the location of certificates used in TLS, TTLS, and PEAP authentication. Any security files that were not installed with the server must be manually installed in these directories.

Server Certificate Path (optional)

Used in EAP-TLS, TTLS, and PEAP message processing. Full path to the RAD-Series Server certificate in `.pem` or `.cer` format. The default is `/etc/opt/aaa/security/rsa_cert.pem`, which is a self-signed certificate created at installation time.

Server Private Key Path

The full path to the private key file associated with the RAD-Series Server certificate for EAP-TLS, TTLS, and PEAP. This file cannot be encrypted. The default is `/etc/opt/aaa/security/rsa_key.pem`.

Client Certificate Authority Path (optional)

Used in EAP-TLS, EAP-TTLS, and EAP-PEAP message processing. Full path to the CA certificate used to sign the RAD-Series Server certificate. The default is `/etc/opt/aaa/security/ca_list.pem`, which is created with the self-signed server certificate at installation time.
Certificate Revocation List Path (optional)

Used in EAP-TLS message processing. Full path to a list of prohibited client certificates in .pem or .cer format. No default is set. If this path is specified but no CRL file is found, the server will not authenticate.

Random Seed Path (optional)

Used in EAP-TLS, EAP-TTLS, and EAP-PEAP message processing. Full path to the random seed file. This file may contain any type of random data. The default is etc/opt/aaa/security/random.rnd, which was created during server installation.

Client User Name Attribute

Used only for TLS authentication. The name in the client certificate used to validate the User Name from the TLS Access-Request. Choose which field and attribute to match:

- **Subject:CommonName** (default) — Use the CommonName (CN) from the Subject field.
- **Subject:EmailAddress** — Use the Email Address (E) from the Subject field.
- **SubjectAltName:RFC822Name** — Use the RFC822Name from the SubjectAltName field of the certificate's subject alternative name extension.
- **Check all attributes** — Search all of the above three fields.

SSL Debug Level (optional)

The minimum RAD-Series server debug level required so that SSL debug output is produced in the radius.debug file. A value of 0 disables SSL debug output.

ECDSA Certificate Path, ECDSA Key Path, ECDHE Parameter Curve (optional)

These parameters must be manually configured. See “Certificate Path Server Properties” on page 209

DHCPv4 Relay Properties

These properties are used to configure the RAD-Series Server as a DHCPv4 relay agent. For more information, see “Using DHCP” on page 84.

DNS Update Properties

These properties determine how the RAD-Series Server resolves IP addresses with DNS.

DNS Refresh Interval

Interval in seconds at which to refresh the IP addresses for Access Devices and Proxies that have been configured by host name. Default is 3600.
DNS Refresh Time Frame

When a DNS entry for a configured client expires (needs refreshing), all other clients that would normally be refreshed within this number of seconds are refreshed immediately. Default is 60.

IP/UDP Properties

These properties configure IP/UDP operations.

Enable IPv6 Communications

This parameter indicates whether the RAD-Series Server will engage in IPv6 communications, i.e. listening on IPv6 interfaces or sending RADIUS packets to/from IPv6 addresses. The default value is NO.

UDP receive buffer size for proxy sockets

This parameter indicates the requested UDP buffer size for a proxy socket. The minimum value is 8192 bytes (8kB); the maximum is 8388608 bytes (8 MB). The default value is 0 which lets the operating system set the UDP receive buffer size.

Default local IPv4 address for IPv4 proxy socket

This parameter specifies the local IPv4 address the RAD-Series Server will use when proxying RADIUS requests via IPv4. The default value is 0.0.0.0, the IPv4 ANY address, which indicates the system will chose the local IPv4 address when transmitting a RADIUS request. This value can be overridden by configuring a Proxy-specific source IP address.

Default local IPv6 address for IPv6 proxy socket

This parameter specifies the local IPv6 address the RAD-Series Server will use when proxying RADIUS requests via IPv6. The default value is ::, the IPv6 ANY address, which indicates the system will chose the local IPv6 address when transmitting a RADIUS request. This value can be overridden by configuring a Proxy-specific source IP address.
RADIUS Listen Socket Properties

These properties configure the sockets on which the RAD-Series Server listens for RADIUS requests.

The following parameters are configured for each listen socket.

IP Address

The IP address can be an IPv4 specific address, an IPv6 specific address, the IPv4 ANY address (0.0.0.0), or the IPv6 ANY address (::). This parameter is required. If the IPv4 ANY address is specified, the server will listen on all IPv4 interfaces. If the IPv6 ANY address is specified, the server will listen for IPv4 and IPv6 messages on all interfaces. There is no default value.

Authentication port

The UDP port number on which to receive authentication requests. The minimum value is 1 and the maximum value is 65535. A value of zero indicates the RAD-Series Server will listen on the Authentication Port specified on the Administration: Start Options screen. There is no default value. If the Authentication Port is not configured, the server will not open an authentication listen socket for the given IP Address.

Accounting port

The UDP port number on which to receive accounting requests. The minimum value is 1 and the maximum value is 65535. A value of zero indicates the RAD-Series Server will listen on the Accounting Port specified on the Administration: Start Options screen. There is no default value. If the Accounting Port is not configured, the server will not open an accounting listen socket for the given IP Address.

Authentication port UDP receive buffer size

This optional parameter indicates the requested UDP buffer size for an auth listen socket. The minimum value is 8192 bytes (8kB); the maximum is 8388608 bytes (8 MB). The default value is 0 which lets the operating system set the UDP receive buffer size.

Accounting port UDP receive buffer size

This optional parameter indicates the requested UDP buffer size for an accounting listen socket. The minimum value is 8192 bytes (8kB); the maximum is 8388608 bytes (8 MB). The default value is 0 which lets the operating system set the UDP receive buffer size.
Message Handling Properties

These properties determine how the RAD-Series Server performs RADIUS message handling.

**Hold Replies**

Number of seconds the RAD-Series Server holds a request after replying to it in case a retransmission is necessary. The default is 6. The value should be twice the default retransmission period of the access devices involved. This does not apply to packets that are forwarded to another server. When set to 0, a special behavior is invoked where the RAD-Series Server does not change the hold time for a request.

*Note:* Using the special value of 0 or a hold time greatly in excess of the retransmission policy of an access device may cause the authentication and accounting queues to grow large, degrading server performance. Tailor this value by the *total* and *holding* values reported on a per-request basis.

**Global Retry Limit**

Maximum number of retransmissions allowed before a RETRY event occurs (a RETRY event is similar to a TIMEOUT event and is handled by the default FSM). The purpose of this is to catch an authentication request and perform some action when a certain number of retransmissions from an access device occur. The default is 0 and no limits are imposed.

**Max. Accounting Requests**

The maximum number of active accounting requests to be handled by the RAD-Series Server within the Hold Replies time. The default is 40,000. When this limit is exceeded, the server drops the request and logs the event.

**Hold Accounting Requests**

The number of seconds the RAD-Series Server holds an accounting request after replying to it. This hold time allows the server to capture duplicate requests. Default is 0. Specify a value that is twice the retransmission interval configured on the access devices. This value overrides the global value set with the Hold Replies parameter.

**Max. Authentication Requests**

The maximum number of active authentication requests to be handled by the RAD-Series Server within the Hold Replies time. Default is 40,000. When this limit is exceeded, the server sends an Access-Reject message and logs the event.

**Hold Authentication Requests**

The number of seconds the RAD-Series Server holds an authentication request after replying to it. This hold time allows the server to capture duplicate requests. Default is 0. Specify a value that is twice the retransmission interval configured on the access devices. This value overrides the global value set with the Hold Replies parameter.
Max. Send Message Size

The maximum size in bytes for an outbound RADIUS packet. The minimum value is 4096. The default value is 16536.

This property is primarily intended for supporting a customized server configuration that might transmit very large packets. Limiting it to be the UDP MTU for the network will prevent excessively large packets from being forwarded (or replied to) in certain circumstances.

Max. Receive Message Size

The maximum size in bytes for an inbound RADIUS packet. The minimum value is 4096. The default value is 16536.

This property is primarily intended for supporting an access client that might transmit very large packets.

Miscellaneous Properties

These properties are used for performance tuning and other RAD-Series Server behavior.

Logfile Compression

This parameter indicates if the old logfile should be compressed when rolled over (by date or by size) to a new logfile. Enabled (Yes) is the default.

Maximum Log File Size

The maximum size in bytes of the server log file and accounting log file. The minimum value for this parameter is 65536; the maximum is 2147483647 (default).

Microsoft Host-Based Authentication

If enabled (Yes), the server will strip "host/" from the EAP-Identity sent by Microsoft clients configured to authenticate as computer on a wireless connection. When using TLS authentication, the remaining string is compared to the selected Client User Name Attribute field in the client certificate. When using PEAP/MSCHAPv2 authentication, the remaining string is used as the inner-realm userid. Enabled (Yes) is the default.

Tunneled EAP MTU Reduction (optional)

The number of bytes by which to reduce the Framed-MTU AVP value when a EAP-PEAP/EAP-TTLS inner (tunnel) request is created. EAP-PEAP and EAP-TTLS must have enough room in the outer packet to contain the inner (tunneled) EAP conversation plus any attributes (such as Reply-Message) that must be sent outside the tunnel during the exchange. This parameter specifies how much of the outer FramedMTU value is reserved for these non-tunneled attributes when constructing an inner reply.
ProLDAP Properties

These properties specify how the RAD-Series Server interacts with LDAP servers. They are global properties used for all LDAP servers.

TLS CA certificate directory

Used if SSL is enabled for the connection to the LDAP servers. The path to a directory containing individual Certificate Authority files. This is used if there is no single TLS CA certificate file specified. There is no default value.

TLS CA certificate file

Used if SSL is enabled for the connection to the LDAP servers. The full path of a single file containing certificates for all the Certificate Authorities that clients will recognize. If defined, this variable will be used instead of the TLS CA certificate directory. There is no default value.

TLS certificate file

The TLS RAD-Series Server certificate file specifies the file that contains the certificate that the RAD-Series Server will use. This parameter is necessary if any of the LDAP directories are configured to use SSL and require validation of the LDAP client certificate. There is no default value.

TLS private key file

The TLS RAD-Series Server private key file specifies the file that contains the private key that the RAD-Series Server will use. This parameter is necessary if any of the LDAP directories are configured to use SSL and require validation of the LDAP client certificate. There is no default value.

OpenLDAP Debug

Enables or disables OpenLDAP debugging. Output is written to the radius.debug file. The default is 0, disabled. A value of -1 maximizes LDAP debugging. See the OpenLDAP documentation for additional debug levels.

NOTE: The OpenLDAP debugging only occurs if the RAD-Series Server debug has been enabled.

LDAP version

This specifies the version of the LDAP protocol to employ. The default value is 3. If your LDAP server requires version 2 of the protocol, enter that number here.

Timeout for TCP connect

The time, in 1/10 seconds, after which the RAD-Series Server stops waiting for a TCP connection to an LDAP server to complete. Default is 30 (3 seconds).
**LDAP timeout**

The time in seconds after which the RAD-Series Server stops sending a request to an LDAP server if it has not replied to the request. Default is 60.

**Minimum wait before retry**

The time in seconds that the RAD-Series Server waits between requests to an LDAP server when there is no current connection for the data store. Default is 1.

**Retry interval**

In the event multiple LDAP servers are configured for a data store and at least one is connected, the interval in seconds at which the RAD-Series Server tries to connect to the remaining LDAP servers. Default is 60 seconds.

**Enable default conf**

This parameter must be manually configured. See “ProLDAP Connection Properties” on page 212.

**Session Properties**

These properties determine how the RAD-Series Server manages sessions.

**Session Pending Timeout**

Time in seconds the RAD-Series Server waits for an Accounting-Start before moving a PENDING session into the UNCONFIRMED state. The default is 15 seconds.

**Session Unconfirmed Timeout**

Time in seconds the RAD-Series Server waits before removing a session in the UNCONFIRMED state. The default is 15 seconds.

**Session Collision Timeout**

Time in seconds the RAD-Series Server waits before removing a session in the COLLISION state. The default is 300 seconds (5 minutes).

**Session MIA Timeout**

Time in seconds the RAD-Series Server awaits the next Interim-Accounting message before moving an ACTIVE session into the MIA state, or before removing a session already in the MIA state. The default is 0, a special value that indicates the RAD-Series Server will measure the time interval between received Interim-Acct messages, and use that measured value to time out subsequent Interim-Acct messages. A positive value represents a fixed time interval which the
RAD-Series Server will use to time out the next expected Interim-Acct message, rather than using a measured interval. A large positive value, e.g. 2147483647 seconds (over 68 years) will effectively cause the server to not terminate a session, or move an ACTIVE session into MIA state, due to the absence of an Interim-Accounting message.

**Session Dropped Timeout**

Time in seconds the RAD-Series Server waits before removing a session in the DROPPED state. The default is 300 seconds (5 minutes).

**Session Finished Timeout**

Time in seconds the RAD-Series Server waits before removing a session in the FINISHED state. Default is 45 seconds.

**Session Table Update Interval**

Time in seconds between updates to the status of sessions. From one to four session timer lists can be created, of increasingly longer update intervals. A given session will reside on at most one timer list. The update interval for the first timer list must be from 1 to 10 seconds, with a default of 5 seconds. Each subsequent timer interval, if any, must be greater than its predecessor. The longest interval cannot exceed 86400 seconds (24 hours). The default is one timer list which is updated every 5 seconds.

**Session Table Checkpoint Interval**

Time in seconds between saving of the sessions to the session.las file by the RAD-Series Server. Default is 300 (5 minutes).

**Session Checkpoint-File Lifetime**

This parameter specifies the age of the oldest session.las file that will be accepted by the RAD-Series Server at startup time. The age is relative to the startup time. The default is 28800 seconds (8 hours). By default, the RAD-Series Server will ignore a session.las file written 8 or more hours before the server startup time. A value of zero indicates the RAD-Series Server should accept the session.las file no matter how old.

**Simultaneous Use**

The maximum number of active sessions users may have, unless a user-specific value is configured that overrides this number. The default value is 1. The value -1 sets no limit. The value 0 prevents access to any user that does not have a specific value configured.

**Simultaneous-Use States**

This parameter defines which session states count towards a user's Simultaneous-Use limit. The default value is “Pending-Active-Unconfirmed-Expired-MIA”, which means that a user session in state PENDING, ACTIVE, UNCONFIRMED, EXPIRED, or MIA will count against the user's
Simultaneous-Use limit. These represent states that are ACTIVE or could become ACTIVE. The other supported value is "Pending-Active", which means that a user session in state PENDING or ACTIVE will count against the user's Simultaneous-Use limit; this is compatible with previous versions of the RAD-Series Server.

**Session Collision Checking**

When this option is set to Yes, the LAS will check if a newly-received authentication request comes from the same NAS (as identified by the NAS-Identifier or NAS-IP-Address or NAS-IPv6-Address attribute) and port (as identified by the NAS-Port attribute) as an existing active session. If so, the existing session is put into a non-active state and the newly-received authentication request becomes the new sole owner of that NAS/Port. When set to No, the RAD-Series Server will not check for concurrent usage of the same NAS and port. This parameter is intended for use by NASes which distinguish their ports and allow only one active session on a given port, to recognize and clear out previous sessions on the given NAS/Port for which the LAS did not receive a termination notice (normally an Accounting-Stop message). The default is Yes.

**Accounting-On / Accounting-Off Support**

When this option is set to Yes, the RAD-Series Server will clear all sessions for a NAS who sends an Accounting Request message with Acct-Status-Type=Accounting-On or Acct-Status-Type=Accounting-Off. When set to No, the Accounting Request will be acknowledged, but the server will take no action regarding the NAS's sessions. The default is Yes.

**Extra Logging**

If set to Yes, the RAD-Series Server will log additional information regarding session events. For example, the RAD-Series Server will always log notifications of unexpected session transitions, such as transitions into COLLISION or UNCONFIRMED states. If this parameter is set to Yes, the RAD-Series Server will also log normal transitions, such as from ACTIVE to FINISHED state. This parameter is intended for those wanting closer monitoring of session events.

**Session-Id Prefix**

The Session-Id-Prefix is an alphanumeric character string, 2 to 8 characters in length. The RAD-Series Server generates a session-id which begins with this character string. The default value is “AAA”. The Session-Id Prefix helps distinguish the Class attribute which contains the RAD-Series Server's session-id from other Class attributes that may be present in a RADIUS message.

**Minimum Interim Accounting Timeout**

This parameter sets a floor for the RAD-Series Server's timeout for the next expected Interim-Acct request message, even if the RAD-Series Server's measured value is less than this value. The default is 60 seconds.

**Interim Accounting Grace Period**

Time in seconds the RAD-Series Server will wait for an Accounting message (Interim or Stop) before removing a session in the MIA state. The default is 15 seconds.
**Maximum Number Of Server-Generated Acct Records per second**

The RAD-Series Server will internally generate an Acct-Stop record for a session which is terminating without benefit of having received an Acct-Stop request from the NAS, such as sessions which terminate in COLLISION or MIA state. The parameter limits the RAD-Series Server's rate of generating such accounting records, to avoid overtaxing of resources. For example, a RAD-Series Server with thousands of sessions might be suddenly tasked with writing many accounting records upon receiving an Accounting-Off request from a NAS; this parameter can be used to distribute that workload over several seconds. The default is 100 server-generated accounting records per second.

**Session Table Limit**

The maximum number of sessions that can be held in the Session Table. When this number is met, authentication requests that would normally result in a new session are ignored. This should not be confused with the session limit of your license. That limits the number of active sessions. The session table has to hold the active sessions and sessions in various other states waiting to be released. Default is 2147483647 (maximum allowed).

**SNMP Properties**

This property, Enable SNMP Support, turns on (Yes) or off (No) SNMP monitoring. The default is No.

For more information, see “Using SNMP” on page 83.

**Tunneling Properties**

These properties configure the RAD-Series Server’s handling of tunneling hints. For more information, see “Tunneling” on page 88.
**Using SNMP**

The RAD-Series Server can exchange information with any Simple Network Management Protocol (SNMP) master agent software that supports the AgentX protocol (see RFC 2741 for more technical information about this protocol).

At startup the server automatically activates its SNMP subagent if SNMP is enabled and the subagent registers the application with the SNMP master agent.

**Enabling and Disabling SNMP**

1. In the Navigation frame, click Server Properties.
2. Click the SNMP Properties link.
3. Click Yes to Enable SNMP or No to Disable SNMP.
4. Click Modify.

**MIB Objects**

Information exchanged through SNMP is represented by objects in the Management Information Base (MIB). The MIB includes extensions for RADIUS authentication and accounting servers that are supported by the RAD-Series Server. The MIB objects that the RAD-Series Server will interpret to the SNMP master agent are defined in the files:

- RADIUS-ACC-SERVER-MIB.txt
- RADIUS-AUTH-SERVER-MIB.txt
- RADIUS-ACC-CLIENT-MIB.txt
- RADIUS-AUTH-CLIENT-MIB.txt

These files can be found in the server’s configuration directory, by default `/etc/opt/aaa/`.

Since the RAD-Series Server performs both authentication and accounting functions, some of the MIB objects return duplicate information. The RAD-Series Server acts as a client when proxying requests.

All of the MIB object requests that are sent by the management workstation to the RAD-Series Server in SNMP requests are read-only, except for radiusAuthServConfigReset and radiusAcctServConfigReset, which allow a write operation.

| Note: When you check the RAD-Series Server status, the server will increase the radiusAuthServTotalAccessRequests count but will not increase radiusAuthServAccessRequests for any client. This behavior will result in a total authentication request count that will not equal the sum of requests received by individual clients. |

See RFCs 4668 thorough 4671 for descriptions of the MIB objects for RADIUS authentication and accounting servers and clients. These MIBs support IPv4 and IPv6 addresses. The older
server MIBs (RFCs 2619 and 2621) have been deprecated and are no longer supported by the RAD-Series Server.

Using DHCP

The RAD-Series Server can be configured to act as a DHCPv4 relay to request IPv4 address assignments from a DHCP server and pass them to an access device. You can associate DHCP address pools with either individual users or realms.

The RAD-Series Server does not support:

• DHCP server failover
• Relay agent information option
• Dynamic DNS updates
• The DHCPv6 protocol, or the assignment of IPv6 addresses
• Communication with the DHCP server via IPv6. Only IPv4 communications are supported.

See RFC 2131 for more technical information about the DHCP protocol.

Required DHCP Server Features

<table>
<thead>
<tr>
<th>Required Features</th>
<th>Recommended Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assign addresses from its IPv4 address pools based on the User Class or Vendor Class Identification attribute.</td>
<td>Assign IPv4 addresses outside the network it resides in. Many RADIUS/DHCP deployments will require this capability. Send to ports above the well-known port range (0-1023). Without this capability the RAD-Series Server will not be able to run as a non-root process.</td>
</tr>
</tbody>
</table>

Process for Using DHCP

To use the RAD-Series Server as a DHCP relay, you’ll need to:

1. Configure the RAD-Series Server for DHCP.
2. Set up realms for DHCP.
3. Define DHCP address pools for realms or specific users.
4. Configure the DHCP server to synchronize with the RAD-Series Server’s DHCP properties.
5. Stop and start the RAD-Series Server. See “Server Administration” on page 32 for instructions.
Configuring the RAD-Series Server for DHCP

1. In the Navigation frame, click Server Properties.
2. Click the DHCP Relay Properties link.
3. On the DHCP Relay screen, select Yes to Enable DHCP Support.
4. Enter either the:
   - DHCP Server Name — fully qualified domain name of the DHCP server
   - DHCP IP Address — IPv4 address of the DHCP server
5. If necessary, change any of the following defaulted values:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCP Server Port</td>
<td>The UDP port on the DHCP server to which DHCP requests are sent. Default is 67.</td>
</tr>
<tr>
<td>DHCP Relay Port</td>
<td>The UDP port on the RAD-Series Server at which DHCP responses are received. Default is 67.</td>
</tr>
<tr>
<td>Client Hardware Type</td>
<td>Value passed to the DHCP server to indicate hardware type. Options are: 0 (NONE) or 1 (ETHER). Default is 1.</td>
</tr>
<tr>
<td>Initial Retransmission Interval</td>
<td>Interval in seconds before the initial retransmission of a request to the DHCP server. Default is 4. The RAD-Series Server will double the retransmission interval for each subsequent retransmission.</td>
</tr>
<tr>
<td>Maximum Retransmission Interval</td>
<td>The maximum interval in seconds at which the RAD-Series Server retransmits DHCP requests. Default is 60.</td>
</tr>
<tr>
<td>Maximum Discover Retransmissions</td>
<td>The maximum number of retransmissions RAD-Series Server makes when acknowledging IP address assignments from the DHCP Server. No default is set.</td>
</tr>
<tr>
<td>Maximum Request Retransmissions</td>
<td>The maximum number of retransmissions RAD-Series Server makes when requesting IP address assignments from the DHCP Server. No default is set.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Maximum DHCP Message Length</td>
<td>The maximum size in bytes of messages that can be received from the DHCP server. No default is set.</td>
</tr>
<tr>
<td>Send Maximum DHCP Message Size Option</td>
<td>If Yes, send the Maximum DHCP Message Size Option to the DHCP server (required by some DHCP servers) in the Discovery message. If No, do not send this option. Default is No.</td>
</tr>
<tr>
<td>Send User Class Option</td>
<td>Specifies which attribute in the DHCP message will carry the IPv4 address pool name. If Yes, the pool name will be sent in the User-Class option. If No, the pool name will be sent in the Vendor-Class-Identifier option. Default is No.</td>
</tr>
</tbody>
</table>

6 Click Modify.

### Setting Up Realms for DHCP
For each realm that will get IP address assignments via DHCP:

1 In the Navigation frame, click Local Realms.
2 Click the realm name link.
3 Click Yes to turn on Session Tracking.

**Note:** Enabling Session Tracking sets the number of individual concurrent sessions to the global Simultaneous Use value set in Session Properties under the Server Properties page. You can override this number by defining a Simultaneous-Use value for an individual user in the user profile.

4 Click Modify.
Defining Address Pools for Specific Users

If the user profile is stored in local storage:

1. In the Navigation frame, click Local Realms for users stored in a realm file or click Users for users stored in the default users file.

2. If you clicked Local Realms then click the button next to the realm name.

3. Click the button next to the User Name.

4. Click the Free tab on the Modify User page.

5. Enter the A-V pair: Address-Pool=name-of-pool

6. Click Modify.

If the user profile is stored in an LDAP directory, add the reply-item attribute to your LDIF file:

aaaReply: Interlink:Address-Pool=name-of-pool

Configuring the DHCPv4 Server

Be sure the following properties on the DHCP server do not conflict with the RAD-Series Server’s DHCP properties:

- The DHCP server’s DHCP Lease value must be greater than the RAD-Series Server’s Session-Kill and Session-Clear values.
- The DHCP server must be configured to match the DHCP Send User Class setting configured on the RAD-Series Server.
Tunneling

The RAD-Series Server establishes tunnels, such as compulsory VPN tunnels, by returning standard RADIUS and vendor-specific tunneling attributes to the client device.

Tunneling Hints

The server resolves tunneling hints in an Access-Request message in this way:

• If all hints match configured attributes, the configured values are returned to the client.
• If some of the hints match configured attributes, both configured values and hints are returned to the client.
• If none of the hints match configured attributes, then all hints and all configured values are returned to the client.

These properties determine RAD-Series Server's tunneling behavior.

Handling requests with no tunneling hints

The drop down menu specifies the behavior when the RAD-Series Server receives an Access-Request that does not contain any Tunnel Hint attributes. The options are:

• Return-Configured-Tunnel-Attributes: Allow the return of tunnel attributes in the authentication reply.
• Return-No-Tunnel-Attributes: Do not return any tunnel attributes in the authentication reply.
• Reject-Access-Request: Fail the authentication by silently discarding the Access-Request.

If no value is selected, Return-Configured-Tunnel-Attributes will be used.

Handling requests with tunneling hints

The drop down menu selects the behavior when the RAD-Series Server receives an Access-Request that contains Tunnel Hint attributes. The options are:

• Accept: Accept and process the received tunnel attributes.
• Discard: Discard the received tunnel attributes. Processing of the Access-Request proceeds as if the tunneling attributes were never present.

If no value is selected, Accept will be used.

Handling requests VSA tunneling hints

The drop down menu lets you select the behavior when the RAD-Series Server receives an Access-Request that contains VSA Tunnel Hint attributes. The options are:

• Accept: Accept and process the received VSA tunnel attributes.
• Discard: Discard the received tunnel attributes. Processing of the Access-Request proceeds as if the tunneling attributes were never present.
proceeds as if the tunneling VSAs were never present.

- Reject: Fail the authentication by sending an Access-Reject

If no value is selected, Accept will be used.

**Tunnel Password Requires Message Authenticator**

This parameter indicates if a Message-Authenticator attribute is required in a RADIUS message containing a Tunnel-Password attribute. The default is No.

---

**Note:** The default is to not enforce the RFC for backwards-compatibility with RAD-Series Server versions prior to 8.1 which didn’t enforce the RFC requirement.
Establishing a Tunnel for a User

If the user profile is stored in local storage, you can add tunneling attributes in Server Manager.

1. In the Navigation frame, click Local Realms for users stored in a realm file or click Users for users stored in the default users file.

2. If you clicked Local Realms then click the button next to the realm name.

3. Click the button next to the User Name to display the User Profile page.

4. Click the Free tab and enter the tunneling attributes one per line in the Reply list box using standard A-V pair syntax:

   attribute = value

5. Click Create or Modify:

You can also configure user tunnel attributes by adding them as reply items to the realm file, default users file or LDAP user profile. For example:

```
user Password = "topsecret",
    session-timeout = 43200,
    idle-timeout = 3600,
    Tunnel-Type = :0:PPTP,
    Tunnel-Medium-Type = :0:IPv4,
    Tunnel-Client-Endpoint = :0:192.168.127.1,
    ...
```

If the user profile is stored in an LDAP directory, you can use an LDIF file to add the tunnel definition to the profile as reply item attributes. Use the syntax:

```
aaaReply: Tunneling-Attribute = :Tag-no:Value
```

For example:

```
aaaReply: Tunnel-Password = :0:Michigan
```
Tunneling Attributes

Tunneling attributes are returned as reply items in a RADIUS Access-Accept message. These tunneling attributes are supported by the RAD-Series Server:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel-Medium-Type</td>
<td>tag-int</td>
<td>Indicates the transport medium to use when establishing the tunnel. See the dictionary for the defined/supported values.</td>
</tr>
<tr>
<td>Tunnel-Type</td>
<td>tag-int</td>
<td>Indicates the tunneling protocol to use when establishing the tunnel. See the dictionary for the defined/supported values.</td>
</tr>
<tr>
<td>Tunnel-Client-Endpoint</td>
<td>tag-str</td>
<td>Address of the client that initiated the tunnel.</td>
</tr>
<tr>
<td>Tunnel-Server-Endpoint</td>
<td>tag-str</td>
<td>Address of the server that provides the tunnel to the user.</td>
</tr>
<tr>
<td>Tunnel-Password</td>
<td>tag-str</td>
<td>Password for access to the machine specified by Tunnel-Server-Endpoint. This is not the password used for authentication.</td>
</tr>
<tr>
<td>Tunnel-Private-Group-ID</td>
<td>tag-str</td>
<td>Group identifier for a private session. Private groups may be used to associate a tunnel with a particular group of users, for example, to route unregistered IP addresses through a particular interface.</td>
</tr>
<tr>
<td>Tunnel-Assignment-ID</td>
<td>tag-str</td>
<td>Indicates what tunnel to use to provide the appropriate level of service. Data transfer for users that share the same assignment are multiplexed over a shared tunnel.</td>
</tr>
<tr>
<td>Tunnel-Preference</td>
<td>tag-int</td>
<td>When using tagged tunnel attributes, indicates each tunnel’s relative level of preference. Specified as an ordinal number: first, second, etc.</td>
</tr>
<tr>
<td>Tunnel-Client-Auth-ID</td>
<td>tag-str</td>
<td>Name used by the client during the authentication that occurs between Tunnel-Client-Endpoint and Tunnel-Client-Server.</td>
</tr>
<tr>
<td>Tunnel-Server-Auth-ID</td>
<td>tag-str</td>
<td>Name used by the server during the authentication that occurs between Tunnel-Client-Endpoint and Tunnel-Client-Server.</td>
</tr>
</tbody>
</table>

Tagged Tunneling Attributes

The AAA software supports tagged attributes that can be used to specify tunneling alternatives, in the event that the access device cannot establish the preferred tunnel configuration.

To specify a tagged attribute, use the syntax:

\[Tunneling-Attribute = :Tag-no:Value,\]

The order in which the access device should consider the tunnel alternatives is specified with the Tunnel-Preference attribute. For example, if Tag set 2 is actually the preferred tunnel, the entry would be:
**Tunnel-Preference = :2:1,**

Some access devices do not support tagged attributes. We recommend that when you return multiple tunnel definitions to a client, you should have at least one set of attributes that is untagged or tagged with a 0 value, so that there is a tunnel definition available to a client that does not support tags.

This example shows two sets of tagged values for the same tunneling attributes.

```
Tunnel-Type = :1:PPTP,
Tunnel-Medium-Type = :1:IPv4,
Tunnel-Client-Endpoint = :1:192.168.127.1,
Tunnel-Server-Endpoint = :1:192.155.111.1,
Tunnel-Password = :1:Michigan,
Tunnel-Private-Group-ID = :1:engineering,
Tunnel-Assignment-ID = :1:management,
Tunnel-Preference = :1:1,
Tunnel-Client-Auth-ID = :1:NET,
Tunnel-Server-Auth-ID = :1:Michigan,
Tunnel-Type = :0:L2TP,
Tunnel-Medium-Type = :0:IPv4,
Tunnel-Client-Endpoint = :0:192.168.127.1,
Tunnel-Server-Endpoint = :0:192.170.130.1,
Tunnel-Password = :0:California,
Tunnel-Private-Group-ID = :0:engineering,
Tunnel-Assignment-ID = :0:management,
Tunnel-Preference = :0:2,
Tunnel-Client-Auth-ID = :0:NET,
Tunnel-Server-Auth-ID = :0:California
```

**Reversing Configuration Changes**

If you do not wish to keep changes you made to the temporary configuration files in Server Manager, you can revert to a previous copy by reloading the original configuration from the RAD-Series Server, provided you haven’t yet saved since loading.
Maintenance

These sections explains the RAD-Series Server functions for:

- Reading the server log file
- Reading accounting logs
- Reporting on server authentication and accounting request statistics
- Reporting on active sessions
- Debugging the server

**Reporting Server Log File**

The RAD-Series Server log file contains a history of server messages generated in response to:

- Server starts/stops
- Internal errors
- Access-Requests and Accounting-Requests

Server logs are, by default, automatically compressed and stored each day in a different file in the server's log file directory (`var/opt/aaa/logs` by default). Logs follow the file naming convention `logfile.yyyymmdd`.

To view server log file messages through the Server Manager:

1. In the Server Status frame, select the server.
2. In the Navigation frame, click Server Logfile.
3. Under Search Parameters, enter any filters to limit the messages displayed.
   - Begin/End — date and time range during which event occurred
   - Number of Records — the maximum number of records to show; may be any number from 1 to 9999
   - User — user name in request; may be just userid (e.g.: fred) or full NAI format name (e.g.: fred@abc.com)
4 Under Message Type, select (Yes) all the types you want displayed and deselect (No) any you do not want.

<table>
<thead>
<tr>
<th>Message Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error/Alert/Critical message</td>
<td>Messages indicating a RAD-Series Server internal error, a serious problem with the configuration files or other severe issues. These should be corrected promptly as they may affect the server operation or ability to provide AAA services. These messages are displayed as message types Error “(E)”, Critical “(C)”, or Alert “(A)” in the physical logfile.</td>
</tr>
<tr>
<td>Warning/Notification message</td>
<td>Messages, flagged as “(W)” in the logfile, indicate a less serious problem, often produced when processing a received request, and can indicate a problem on the client’s end. They should be corrected as they may impact the ability of some users to obtain AAA services, though the correction may well involve the NAS rather than the RAD-Series Server. Notification messages, flagged as “(N)” in the logfile, are indications of noteworthy events, such as the receipt of a HUP signal by the server.</td>
</tr>
<tr>
<td>Information</td>
<td>All messages that are not one of the above types. They are usually confirmation messages about server setup or usage. Informational messages, flagged as “(I)” in the logfile, are generated for start up messages and messages generated for each Accounting-Request message that is received. Other messages flagged as “(I)” in the logfile are not reported in this category but have their own category, such as authentication requests. By default, these types are not displayed.</td>
</tr>
<tr>
<td>Server start/restart</td>
<td>Messages generated during each server startup or restart.</td>
</tr>
<tr>
<td>Server stop</td>
<td>Messages generated when the administrator shuts down the server.</td>
</tr>
<tr>
<td>Authentication request (grey)</td>
<td>Access-Request message received.</td>
</tr>
<tr>
<td>Authentication failure (red)</td>
<td>Access-Reject message sent.</td>
</tr>
<tr>
<td>Authentication success (green)</td>
<td>Access-Accept message sent.</td>
</tr>
<tr>
<td>Accounting response (blue)</td>
<td>Accounting-Request response message sent.</td>
</tr>
</tbody>
</table>

5 Click Search to display the log file results.
You’ll see the Type, Time, and Description for each message displayed in the Message frame.
Reporting User Accounting Records

The RAD-Series Server records session information in an active session table record. When the server receives an Accounting-Request to stop the session, this information is written to the server’s accounting log file.

By default, accounting log files are written in MERIT standard format in `/var/opt/aaa/acct/session/yyyy-mm-dd.log`. See “Accounting Record Format” on page 96 for a description of log file information.

You can control the session logging behavior by changing when the server’s Finite State Machine (FSM) calls the LOG action. See “Modifying Accounting Logging Behavior” on page 100.

**Note:** Not all wireless access points support RADIUS account logging. You should verify support with the access point vendor.

Viewing the Accounting Log

To view accounting log records in Server Manager:

1. In the Server Status frame, select the server.
2. In the Navigation frame, click Accounting.
3. Under Search Parameters, enter any filters to limit the records displayed:
   - Begin/End — date and time range during which session occurred
   - Number of Records — the maximum number of records to show; may be any number from 1 to 999
   - User — user name; may be just userid (e.g.: fred) or full NAI format name (e.g.: fred@abc.com)
   - Realm — realm name; if no User specified, pulls all records from this realm that match the other criteria

   **Note:** Enter NULL to display NULL realm records. Don’t leave the field blank.

   - NAS — network access server from which the accounting message originated; may use NAS-Identifier, NAS-IP-Address or NAS-IPv6-Address

   **Note:** This parameter will find a leading substring or an exact match. For example, a value of t14 would match records with NAS/Port field t14.interlinknetworks.com/1234)

Accounting Record Format

In the default MERIT format, the first line of an accounting record contains 14 tab delimited fields that represent the user session information. If a value does not exist, NA appears as the value’s placeholder.

The first line of an accounting record contains:

\[
\text{LAS-Start} \quad \text{Session-State} \quad \text{LCL-Time} \quad \text{LAS-Duration} \quad \text{LCL-Duration} \quad \text{User-Name} \quad \text{Authenticated-User-Name} \quad \text{Session-ID} \quad \text{Token} \quad \text{Session-Timeout} \quad \text{NAS/Port} \quad \text{Service-Class} \quad \text{Filter-ID} \quad \text{Service-Type}
\]

After the first line, each A-V pair in the Accounting-Request-Stop message is listed, preceded by the characters “##.”

**Note:** The default format is specified by the “log_v2_0” setting for the AATV parameter in the log.config file. Alternate formats, including Livingston Call Detail Records, may be specified but the Server Manager will only report accounting logfiles in Merit “log_v2_0” format.

Accounting Attributes

These attributes appear on the first line of the MERIT accounting record:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LAS-Start (epoch)</td>
<td>Time when session started (in seconds), relative to 1/1/1970.</td>
</tr>
<tr>
<td>Session-State</td>
<td>State of the session when record was logged. Codes are:</td>
</tr>
<tr>
<td></td>
<td>• ACTIVE</td>
</tr>
<tr>
<td></td>
<td>• FINISHED</td>
</tr>
<tr>
<td></td>
<td>• UNCONFIRMED</td>
</tr>
<tr>
<td></td>
<td>• MIA</td>
</tr>
<tr>
<td></td>
<td>• DROPPED</td>
</tr>
<tr>
<td></td>
<td>• COLLISION</td>
</tr>
<tr>
<td></td>
<td>• No-Session</td>
</tr>
<tr>
<td></td>
<td>• Not-Local</td>
</tr>
<tr>
<td>LCL-Time (r-epoch)</td>
<td>Time when record was logged, relative to LAS-Start.</td>
</tr>
<tr>
<td>LAS-Duration (integer)</td>
<td>Duration of session (in seconds) according to the RAD-Series Server.</td>
</tr>
<tr>
<td>NAS-Duration (integer)</td>
<td>Duration of session (in seconds) according to the NAS, per the NAS's Acct-Session-Time attribute.</td>
</tr>
<tr>
<td>User-Name (special)</td>
<td>User-Id &quot;@&quot; User-Realm from RADIUS User-Name attribute. If realm uses a tunneled authentication method, this field will show the outer user identity.</td>
</tr>
</tbody>
</table>
Accounting Record Extensions

Standard Accounting RFC extensions may appear in a RAD-Series Server accounting record in addition to the basic session information. These extensions are the A-V pairs sent from the client in the Accounting-Request-Stop message. See the Accounting Extensions section of the dictionary file for a list of valid A-V pairs.

Access Device Values

Vendor-specific attributes (VSAs) related to the access device may appear among the accounting record extensions. These represent attribute values that describe the access device used for authentication and authorization. Valid attributes are defined in the dictionary file. You may

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authenticated-User-Name</td>
<td>If realm uses a tunneled authentication method, this field will show the authenticated Inner-Identity value. Otherwise, always shows the RADIUS User-Name value. You must enable session tracking for the outer realm to see this value. Doing so will also limit each user in this realm to the number of concurrent sessions you have defined with the Simultaneous-Use parameter of las.conf.</td>
</tr>
<tr>
<td>Session-ID (string)</td>
<td>Session ID, as assigned by the RAD-Series Server (is unique to each session).</td>
</tr>
<tr>
<td>Token (string)</td>
<td>Token pool name for the first generic tokenpool used by this session, else NA.</td>
</tr>
<tr>
<td>Session-Timeout (integer)</td>
<td>Session Time limit.</td>
</tr>
<tr>
<td>NAS/Port (special)</td>
<td>NAS-Identifier ”/” NAS-Port-Number.</td>
</tr>
<tr>
<td>An obsolete field</td>
<td>Always NA.</td>
</tr>

extend the VSA list by adding the vendor to the "vendors" file and the attributes and their values to the "dictionary" file.

**Example Accounting Record**

```
1353084227 FINISHED 4 4 NA t20021@pap.com t20021@pap.com
'AAA.50a66d43.0001' NA NA t32.iln.com/2002 NA NA NA
## User-Name:0='t20021@pap.com'
## NAS-IP-Address:2=192.168.3.32
## Acct-Input-Octets:1=16
## Acct-Input-Packets:1=2
## Acct-Output-Octets:1=4
## Acct-Output-Packets:1=4
## Acct-Authentic:1=RADIUS Acct-Delay-Time:1=0
## Acct-Status-Type:1=Stop
## Session-Tracking-Status:1=Have-Session
## Session-Start-Time:3='2012-11-16 16:43:47'
## Session-End-Time:3='2012-11-16 16:43:51'
```  

**Modifying the Accounting Log**

Certain features of the standard RAD-Series Server accounting log format can be reconfigured through the "log.config" file.

**Writing CDR Accounting Records**

You can configure the server to write Accounting log records in the Livingston Call Detail Record (CDR) format, rather than, or in addition to, the default MERIT format.

If you change radius.fsm to call ACCT rather than LOG for each logged message event, logs will be stored in an alternate directory (/var/opt/aaa/radacct).

1. In a text editor, open the "log.config" file found in the server’s configuration file directory. Locate the following line, which should be found near the beginning of the file:
   ```
aatv log_v2_0
   ```
2. Change `aatv log_v2_0` to `aatv log_acct`
3. Save and close the file.
4. Stop and start the server.

**Changing the Accounting Log Filename**

1. In a text editor, open the "log.config" file found in the server’s configuration file directory. Locate the following line, which should be found near the beginning of the file:
   ```
filename session.%Y-%m-%d.log
   ```
2 Change session.%Y-%m-%d.log to the filename syntax you wish to use.
3 Save and close the file.
4 Stop and start the server.

### Changing the Accounting Log Rollover Interval

The log rollover interval specifies how often a new log file is created to store accounting records. The interval is determined by the finest unit of time in the timestamp portion of the filename.

If gzip is in your UNIX path, log files can be automatically compressed when they rollover by adding a `on-endfile "gzip -9 !"` to the log.config file.

1 In a text editor, open the log.config file found in the server’s configuration file directory. Locate the following line, which should be found near the beginning of the file:
   ```
   filename session.%Y-%m-%d.log
   ```

2 Rename the file to reflect the rollover interval. For example, for hourly rollover:
   ```
   %Y-%m-%d-%H
   ```

3 Save and close the file.
4 Stop and start the server.
Modifying Accounting Logging Behavior

You can change the RAD-SeriesServer’s logging behavior by modifying the server’s radius.fsm file.

All RADIUS accounting message types marked LOG are logged by the server. To log any type of accounting messages, simply change the action to LOG for the event handler that corresponds to the message. These should always take the next action ReplyHold.

Interim Accounting Logging

To indicate that a session is still active, a client may send an Accounting-Alive (Accounting-Interim-Update) message at regular intervals during the session. To generate logs when the server receives this message, rather than wait for Accounting-Stop:

1. In a text editor, open the file radius.fsm (found in /etc/opt/aaa by default).

2. Find the lines:
   
   ```
   AcctLog:
   
   *.*.ACCT_START ReplyPrep ReplyPolicyHold
   *.*.ACCT_STOP LOG ReplyHold
   *.*.ACCT_ALIVE ReplyPrep ReplyPolicyHold
   ```

3. Change:

   ```
   *.*.ACCT_ALIVE ReplyPrep ReplyPolicyHold
   ```

   To:

   ```
   *.*.ACCT_ALIVE LOG ReplyHold
   ```

4. To turn on logging for any other message types:

   - Change ReplyPrep to LOG
   - Change ReplyPolicyHold to ReplyHold.

   To turn off logging, reverse the settings.

5. Save and exit radius.fsm.

6. Stop and start the server.

Proxy Accounting Messages

Normally, the server logs all accounting messages locally. To log messages on a central server, follow the steps in “Proxying Accounting Requests to a Central Server” on page 49 to change the .fsm settings.
Reporting Server Statistics

Use the Server Manager Statistics page to retrieve a count of selected events that occurred on the RAD-Series Server within a given time period. Statistics are displayed using a bar graph. You’ll see the total number of:

- Server starts
- Server stops
- Accounting-Requests
- Authentication-Requests
- Authentication-Successes
- Authentication-Failures

1. In the Server Status frame, select the server.
3. Under Search Parameters, enter the Begin and End date and time of the period for which to retrieve statistics.
4. Click Search.
Reporting Active Server Sessions

If the RAD-Series Server is tracking sessions for a given realm, a session table entry is set up when the user is authenticated and the server returns an Access-Accept. The session entry remains active until the session is terminated for some reason, such as the receipt of an Accounting-Stop request from the access device (the normal case), or if the server itself terminates the session due to, say, a session collision or an Interim-Accounting timeout. Accounting messages are logged to the accounting logfile when received. Which accounting messages are logged depends on the FSM you are using. The default FSM only logs Accounting-Request-Stop messages. The logall.fsm FSM will log all the accounting messages.

---

**Note:** Not all wireless access points support RADIUS session-based account logging. Verify support with the access point vendor.

---

Viewing Active Sessions

1. In the Server Status frame, select the server.
2. In Navigation frame, click Sessions.
3. Enter the Session Filtering parameters.
   - You can enter either or both values. Only sessions matching these values will be retrieved.
4. Click Display.
   - The Workspace display changes to show a list of active sessions.
5. Click a user session link to display the session attributes.
6. Click OK to return to the active session list.

Stopping Active Sessions

To clear sessions that were terminated on the access device but are maintained as active by the RAD-Series Server:

1. Follow the procedure Viewing Active Sessions.
2. Click Stop.
   - The RAD-Series Server will clear the record from its active session table, but no action is taken by the access device.

---

**Note:** You can only stop a session on a server that contains a self-referring client entry. When you install a RAD-Series Server, it automatically adds this entry (localhost) to the server’s Proxies configuration.
Overview of the Server’s Session Management

If the RAD-Series Server is managing a session for a particular user, the server will allocate an internal data structure, called a session entry, in which information about the user’s session is held and updated. The session entry structure information includes session identification parameters (User-Name, NAS-Identifier, NAS-Port, session id, Acct-Session-Id, etc) as well as the attributes from the last received accounting request.

Session States

A session will be in one of the following states: PENDING, ACTIVE, FINISHED, UNCONFIRMED, MIA, DROPPED, COLLISION, or RELEASING. These states are defined in the dictionary’s Session-State attribute.

A session will normally transition from PENDING to ACTIVE to FINISHED, after which the session ends and the session entry is deallocated.

The normal session states, and the events which cause a transition from one state to another are these:

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PENDING</td>
<td>This is the first state for a session. When the server successfully processes an Access-Request and returns an Access-Accept, the session entry is created and the session is placed in PENDING state, pending the arrival of the expected Accounting-Start message.</td>
</tr>
<tr>
<td>ACTIVE</td>
<td>This is the steady state in which a session normally resides. When the expected Accounting-Start message is received for a session in PENDING state, the session transitions into ACTIVE state. The session will normally stay in ACTIVE state until an Accounting-Stop message is received, signaling the end of the access device’s session. If Interim-Accounting messages are received for an ACTIVE session, the session remains in ACTIVE state.</td>
</tr>
<tr>
<td>FINISHED</td>
<td>When an Accounting-Stop is received, an accounting record is normally written, and the ACTIVE session will transition into FINISHED state. The session entry will remain in FINISHED state for a configurable time (Session-Finished-Timeout), and then the session entry will be deleted.</td>
</tr>
</tbody>
</table>
The arrival of unexpected messages or the failure of expected messages to arrive in a timely manner may cause a session to transition into UNCONFIRMED, EXPIRED, MIA, DROPPED, COLLISION, or RELEASING state:

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNCONFIRMED</td>
<td>If a session in PENDING state does not receive the expected Accounting-Start message within a configurable time (Session-Pending-Timeout), the session enters UNCONFIRMED state. If an UNCONFIRMED session does not receive an Accounting message within a configurable time (Session-Unconfirmed-Timeout), the session is terminated and the session entry is deallocated. If an Accounting message is received before the Session-Unconfirmed-Timeout expires, the session will transition into ACTIVE (for an Acct-Start or Interim-Acct) or FINISHED (for an Acct-Stop).</td>
</tr>
<tr>
<td>COLLISION</td>
<td>If Collision-Checking is enabled and the server receives a new Access-Request whose NAS-Identifier and NAS-Port match those of an existing session which is in PENDING or ACTIVE or UNCONFIRMED or MIA state, the existing session is placed in COLLISION state. The session will remain in COLLISION state for a configurable period of time (Session-Collision-Timeout), after which the session is terminated and the session entry is deallocated. The receipt of an Acct-Stop before the Session-Collision-Timeout expires will transition the session into FINISHED state.</td>
</tr>
<tr>
<td>DROPPED</td>
<td>If the server receives an Accounting-Request from an access device with an Acct-Status-Type of Accounting-On or Accounting-Off, this indicates that all sessions from this access device should be terminated. The server will transition any sessions for this device which are in ACTIVE or PENDING or UNCONFIRMED or MIA state, into DROPPED state. A session will remain in DROPPED state for a configurable period of time (Session-Dropped-Timeout), after which the session is terminated and the session entry is deallocated. The receipt of an Acct-Stop before the Session-Dropped-Timeout expires will transition the session into FINISHED state.</td>
</tr>
<tr>
<td>MIA</td>
<td>Once the server receives an Interim-Accounting message for session in ACTIVE state, the server will expect to receive further Interim-Accounting messages periodically. The Interim-Accounting messages act as a keepalive for the session. If a subsequent expected Interim-Accounting message does not arrive in a timely manner, the session is placed into MIA state. The session will remain in MIA state for a configurable period of time (Session-MIA-Timeout), after which the session is terminated and the session entry is deallocated. The receipt of an Interim-Accounting message before the Session-MIA-Timeout expires will transition the session back into ACTIVE state. The receipt of an Acct-Stop before the Session-MIA-Timeout expires will transition the session into FINISHED state.</td>
</tr>
<tr>
<td>RELEASING</td>
<td>If a PENDING session entry has been created for a newly authenticated session during the processing of an Access-Request, but some subsequent FSM or POLICY step causes the server to reject the Access-Request, the session will transition into RELEASING state. A session entry in RELEASING state will be quickly deallocated.</td>
</tr>
</tbody>
</table>
Concurrent Session Limits

A user session which is in ACTIVE state, or in a state which could become ACTIVE (PENDING, UNCONFIRMED, or MIA), will count towards the server’s overall license limit, and will count towards that user’s Simultaneous-Use limit.

Accounting records generated by the server

If a session terminates for which the server has not received an Accounting-Stop from the access device, the server will internally generate an Acct-Stop message for this session based on information the server has saved in the session entry. This happens when a session expires in the UNCONFIRMED, COLLISION, MIA, or DROPPED states. The server-generated Accounting-Stop will be logged in the accounting log file, available for network management, auditing, or billing. A server-generated accounting record can be recognized by its session state of UNCONFIRMED, COLLISION, MIA, or DROPPED.

The server’s algorithm for measuring Interim-Accounting intervals

The Session-MIA-Timeout is the time in seconds the RAD-Series Server awaits the next Interim-Accounting message before moving an ACTIVE session into the MIA state, or before removing a session already in the MIA state. The default of Session-MIA-Timeout is 0, a special value that indicates the RAD-Series Server will measure the time interval between received Interim-Acct messages, and use that measured value to time out subsequent Interim-Acct messages. This section describes the server’s algorithm by which this interval is determined.

1) The server measures the time T, which is the time between the receipt of the Accounting-Start and the receipt of the first Interim-Accounting message. The value of T, plus a small configurable delta value, will represent the maximum time the server will wait for the next expected Interim-Accounting message.

2) The configurable delta value is the Session-MIA-Grace-Period, and its default value is 15 seconds. The delta value provides for small variations in the delivery interval of Interim-Accounting messages, to allow for network transit time, retransmissions, etc.

3) As each subsequent Interim-Accounting message is received, the value of T is recalculated. The recalculations of T is as follows: T is set to the minimum of [a] the previous value of T, and [b] the measured time period between the current time and time when the previous Interim-Accounting was received. The idea is that the server will shorten the expected time T if the initial Interim-Accounting message was lost, i.e. the first measurement of T had inadvertently measured the time between the Accounting-Start and the 2nd Interim-Accounting message.

4) If the session is in the ACTIVE state and if time period T+delta expires without the receipt of an Interim-Accounting message, the session will move into MIA state and stay in the MIA state for a maximum of another T+delta seconds. This MIA state timer value allows for two consecutive Interim-Accounting messages to be lost before the session is declared finished.

5) If an Interim-Accounting message is received while the session is in MIA state, the session transitions back into ACTIVE state.

6) If the state timer expires while the session is in MIA state, the session terminates: the session entry is removed from the session table and the session entry is deallocated.
Server Programs

**radUSD**

radUSD is the main RAD-Series Server program, used to handle Access-Requests and Accounting-Requests from RADIUS clients. Authentication and accounting requests come to radUSD in the form of UDP packets conforming to the RADIUS protocol.

Message processing is based upon a finite state machine that radUSD loads into memory when it is first started. You can configure which finite state machine the RAD-Series Server loads upon startup with the `-f FSM-file` option, but it is static after server startup.

radUSD runs as a daemon that you can start from the Server Manager console, the command line or through an inetd service.

**Synopsis**

```
radUSD -c <Working-directory> -p <Authentication-port>
         -pp <Authentication-relay-port> -q <Accounting-port>
         -qq <Accounting-relay-port> -da <AATV-directory>
         -d <Config-directory> -dl Logfile-directory> -l <Log-format>
         -di <IPC-directory> -dm <Accounting-directory> -a <Livingston-directory>
         -dd <Data-directory> -dr <Run-directory> -f <FSM>
         -g {syslog|logfile|stderr} -h -n -s -v -z -x
```

**Options**

You can start radUSD with any of the following options to override built-in defaults. Server startup options can also be changed in the Server Manager.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-c &lt;Working-directory&gt;</code></td>
<td>New current working directory. If you specify this directory, you can use paths relative to the working directory for subsequent radUSD directory options.</td>
</tr>
<tr>
<td><code>-p &lt;Authentication-port&gt;</code></td>
<td>Default port number to listen for authentication requests on. See “Managing RADIUS Listen Sockets” on page 264 for a complete description.</td>
</tr>
<tr>
<td><code>-pp &lt;Authentication-relay-port&gt;</code></td>
<td>Default port number to relay authentication requests to, if the remote server uses a port other than UDP standard 1812 for authentication requests.</td>
</tr>
<tr>
<td><code>-q &lt;Accounting-port&gt;</code></td>
<td>Default port number to listen for accounting requests on. See “Managing RADIUS Listen Sockets” on page 264 for a complete description.</td>
</tr>
<tr>
<td><code>-qq &lt;Accounting-relay-port&gt;</code></td>
<td>Default port number to relay accounting requests to.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-da &lt;AATV-directory&gt;</td>
<td>Location of binary AATVs, if other than installation default.</td>
</tr>
<tr>
<td>-d &lt;Config-directory&gt;</td>
<td>Location of configuration files.</td>
</tr>
<tr>
<td>-dl &lt;Logfile-directory&gt;</td>
<td>Server log file directory. Default is /var/opt/aaa/logs.</td>
</tr>
<tr>
<td>-l &lt;Logfile-name&gt;</td>
<td>Server log file name. Default is logfile.%Y%m%d.</td>
</tr>
<tr>
<td>-di &lt;IPC-directory&gt;</td>
<td>Location of shared memory operation files. The default is &quot;/var/opt/aaa/ipc&quot;</td>
</tr>
<tr>
<td>-dm &lt;Accounting-directory&gt;</td>
<td>Location of accounting session records in MERIT format.</td>
</tr>
<tr>
<td>-a &lt;Livingston-directory&gt;</td>
<td>Location of Livingston Call Detail Records (when used as an alternative to the default MERIT format).</td>
</tr>
<tr>
<td>-dd &lt;Data-directory&gt;</td>
<td>Location of active session information stored in the session.las file. The sesstab utility requires that this option be defined if the server has been installed in a nondefault location.</td>
</tr>
<tr>
<td>-dr &lt;Run-directory&gt;</td>
<td>Location of the file where the server's process ID is stored.</td>
</tr>
<tr>
<td>-f &lt;FSM&gt;</td>
<td>Alternate FSM file to load upon startup, instead of the default radius.fsm file.</td>
</tr>
<tr>
<td>-g {logfile</td>
<td>syslog</td>
</tr>
<tr>
<td>-h</td>
<td>Display the help syntax.</td>
</tr>
<tr>
<td>-n</td>
<td>Start new session table for LAS upon server startup.</td>
</tr>
<tr>
<td>-s</td>
<td>Run in single process (non-spawning) mode.</td>
</tr>
<tr>
<td>-v</td>
<td>Display radiusd version information.</td>
</tr>
<tr>
<td>-x</td>
<td>Add to debug flag value, repeat the –x from one to four times to enable 1 to 4 levels of debugging. These switches should follow all other switches.</td>
</tr>
<tr>
<td>-z</td>
<td>Empty (zap) the log file &amp; debug file.</td>
</tr>
</tbody>
</table>
**radiusd.sh**

*radiusd.sh* is a script that can be used to start the RAD-Series Server at boot time.

**Synopsis**

```
radiusd.sh start|stop|restart|reload|status
```

**Arguments**

The ‘start’ argument will start the RAD-Series Server if it is not already running.

The ‘stop’ argument will stop the RAD-Series Server if it is running.

The ‘restart’ argument will stop the RAD-Series Server if it is running and then start it back up.

The ‘reload’ argument will HUP the RAD-Series Server if it is running so that it can re-read its configuration files.

The ‘status’ argument will report the current status of the RAD-Series Server.
**radcheck**

*radcheck* determines whether a given RAD-Series Server is operational. *radcheck* may be invoked from any host, not just those registered in the clients file, although more information is returned to those so registered.

See “Reporting Server Status” on page 36 for a description of *radcheck* output.

**Synopsis**

```
radcheck -d <Directory> -h -ipv6 <on/off> -p <UDP-port> -r <Retries> -t <Timeout> -v -writesess -x -0 <ServerName>
```

**Arguments**

<ServerName> IPv4 address, IPv6 address or fully-qualified domain name which maps to an IP address on which the RAD-Series Server is listening.

**Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-d &lt;Directory&gt;</code></td>
<td>The directory containing the RAD-Series Server dictionary and clients files, instead of the default <code>/etc/opt/aaa</code> directory. If no <code>-d</code> option is given, <em>radcheck</em> will look in the default location. An error is displayed if the configuration files cannot be found.</td>
</tr>
<tr>
<td><code>-h</code></td>
<td>Display the <em>radcheck</em> syntax.</td>
</tr>
<tr>
<td><code>-ipv6 &lt;on/off&gt;</code></td>
<td>Enable/Disable IPv6 communications. If value is <code>'on'</code> then the status request will be sent using IPv6. If the value is <code>'off'</code> then the request will be sent using IPv4. The default is off.</td>
</tr>
<tr>
<td><code>-p &lt;UDP-port&gt;</code></td>
<td>A UDP port on which the RAD-Series Server is listening for authentication requests. The default value is 1812.</td>
</tr>
<tr>
<td><code>-r &lt;Retries&gt;</code></td>
<td>Maximum number of retries instead of the default of 10.</td>
</tr>
<tr>
<td><code>-t &lt;Timeout&gt;</code></td>
<td>Alternate timeout value (in seconds) instead of the default of 3.</td>
</tr>
<tr>
<td><code>-v</code></td>
<td>Display <em>radcheck</em> version information.</td>
</tr>
<tr>
<td><code>-writesess</code></td>
<td>Force the RAD-Series Server to checkpoint the session table when the <em>radcheck</em> request is processed. This is of benefit to users who will be doing a subsequent sesstab inquiry and wants the most-current session information.</td>
</tr>
<tr>
<td><code>-x</code></td>
<td>Add to debug flag value.</td>
</tr>
<tr>
<td><code>-0</code></td>
<td>Suppress copyright message in the output.</td>
</tr>
</tbody>
</table>
radpwtst

radpwtst is a test client program. It generates RADIUS packets to perform a password authentication on a specified user using the current RAD-Series Server configuration.

If the authentication succeeds, radpwtst displays “authentication OK” on standard output. Otherwise, radpwtst displays “User-Name authentication failed.”

radpwtst can also send accounting requests. When a response is received, radpwtst displays “Accounting Response received.”

Synopsis

```
radpwtst -a <ACKs> -c <Code> -d <Directory> -f <File> -g <Group> -h -i <client-id> -ipv6 <on/off> -l <NAS-Port> -n -p <UDP-port> -r <Retries> -s <Servername> -secret <secret> -t <Timeout> -u <Type> -v -w <Password> -x -z <Challenge-password> -:<attribute=value> -0 <User-Name>
```

Arguments

`<User-Name>` User-Name to send with the test request. If no realm is specified, the server looks for the user in the NULL realm data store. By default, the NULL realm data store is the `users` file distributed with the server.

Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a &lt;ACKs&gt;</td>
<td>Number of responses to ignore. Used to test possible retransmission problems.</td>
</tr>
<tr>
<td>-c &lt;Code&gt;</td>
<td>RADIUS packet type codes from the following list:</td>
</tr>
<tr>
<td></td>
<td>1: Access-Request</td>
</tr>
<tr>
<td></td>
<td>4: Accounting-Request</td>
</tr>
<tr>
<td></td>
<td>n: Packet code n, 0 &lt;= n &lt;=255</td>
</tr>
<tr>
<td>-d &lt;Directory&gt;</td>
<td>The directory containing the server’s clients, dictionary, and vendors files, instead of the default <code>/etc/opt/aaa</code> directory. If no -d option is given, radpwtst will look for the default location. An error will be displayed if the configuration files cannot be found.</td>
</tr>
</tbody>
</table>
The value can be a DNS name, an IPv4 or IPv6 address. If it is a DNS name, it is mapped into an IPv4 or IPv6 address. The final IP address, as determined by –i, is sent as the NAS-IP-Address attribute or the NAS-IPv6-Address attribute.

And “-i -1” (client-id of -1), the special value of -1 tells radpwtst to NOT SEND a NAS-IP-Address. This might be of use to someone that wants to instead send NAS-Identifier and suppress the NAS-IP-Address.

The default is the originating machine’s IP address.

If the value is ‘on’ then the request will be sent using IPv6. If the value is ‘off’ then the request will be sent using IPv4. The default is Off.

The NAS port number to send instead of the default of 1.

And if “-l -1” (NAS-Port od -1), the special value -1 tells radpwtst to NOT SEND a NAS-Port attribute. This might be of use to someone who doesn’t want to send NAS-Port at all, or wants to send NAS-Port-Type instead.

Forces the Authentication-Only value to be used in the Service-Type A-V pair.

An alternate UDP port number. For an Access-Request the default UDP port number is 1812 or the number specified in the /etc/services file for radiusd. For an Accounting-Request the default port number is 1813 or the number specified in the /etc/services file for radacct.

Maximum number of retries instead of the default of 10.
Stopping Sessions Using radpwtst

You can clear sessions with radpwtst. To clear a session, you must know its Session-Id (Class attribute value), which you can determine by running sesstab. The following command line will manually stop a session by sending an Accounting-Request stop message:

```
-s <servername>
-secret <secret>
-t <Timeout>
-u <Service-Type>
-v
-w <Password>
-x
-z <Challenge-password>
-<attribute=value>
-0
```

Option Description
---
-s <servername> An alternate server instead of the built-in default of radius.localdomain.
-secret <secret> Shared secret (no default). If not specified, radpwtst will look in the clients file for the shared secret.
-t <Timeout> Timeout value (in seconds) instead of the default of 3.
-u <Service-Type> This specifies the Service-Type to send instead of using the default auth value. Note, that the default auth value will fail if no password (or an empty password) is included in the Access-Request (default or -c 1) produced by radpwtst. RADIUS server requires a valid (nonempty) password be provided in Access-Request packets where the Service-Type is Authenticate-Only.

Valid Service-Type values are:

- admin
- auth
- dumb
- exec
- outbound
- ppp
- slip
- dbadmin
- dbdumb
- dbppp
- dbslip

Note: db stands for dial back in the last four types.

-v Displays the radpwtst version.
-w <Password> Password to use, instead of being prompted for one.
-x Increases the debug level which displays additional debug output and account logging on the screen.
-z <Challenge-password> Challenge password to use in response to an Access-Challenge, instead of being prompted for one.
-<attribute=value> One or more A-V pairs to add to the test request.
-0 Suppress copyright message in the output.

Stopping Sessions Using radpwtst

You can clear sessions with radpwtst. To clear a session, you must know its Session-Id (Class attribute value), which you can determine by running sesstab. The following command line will manually stop a session by sending an Accounting-Request stop message:
radpwtst -c 4 -s <Server FQDN>|<Server IP-Address> -i <NAS-IP-address> -l <Port> -:Acct-Status-Type=Stop -p 1813 -:Class="<class-value>"
radsignal

The radsignal utility performs 3 functions:

- Turns debugging on and off or sets the level of debug output, while the RAD-Series Server is running. This function replaces raddbginc.
- Initiate server logfile rollover.
- Initiate accounting stream file rollover.

Synopsis

```
radsignal -h -v
radsignal -di <IPC-directory> <pid> debug <delta>
radsignal -di <IPC-directory> <pid> roll logfile
radsignal -di <IPC-directory> <pid> roll stream <stream-name>
```

Arguments

<pid> The process ID of radiusd (the RAD-Series Server program). You can determine this by running:

```
ps -eaf | grep radiusd
```

<delta> The number of debug levels to increment from the current level (not the number of the level you want). The debug level will not increase past level 4. 0 turns debugging off. All debug output is sent to the radius.debug file in /var/opt/aaa/logs or in an alternate location specified by the radiusd -dl option.

<stream-name> The name of the accounting stream to roll. If one is not specified then the default stream (*default*) is used.

data, roll logfile, and roll stream are keywords that identify the invocation desired and are described below after the options.

Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-di &lt;IPC-directory&gt;</td>
<td>IPC directory path; required if radiusd installed in a non-default location.</td>
</tr>
<tr>
<td></td>
<td>&lt;IPC-directory&gt; must match the path given by the radiusd -di option.</td>
</tr>
<tr>
<td></td>
<td>The default is &quot;/var/opt/aaa/ipc&quot;</td>
</tr>
<tr>
<td>-h</td>
<td>Displays the radsignal syntax and can not be combined with other options.</td>
</tr>
<tr>
<td>-v</td>
<td>Displays the radsignal version and can not be combined with other options.</td>
</tr>
</tbody>
</table>
**Description** debug

This form of invocation specifies that you wish to change the level of debug output generated by radiusd. You can use the radsignal command to turn debugging on and off or set the level of output while the RAD-Series Server is running using radsignal. Debugging output by the server can also be turned on when starting the server at a specified level of output. All of the debug output is sent to the radius.debug file, in the default directory or in an alternate location specified by the radiusd -dl option.

**Debug Levels**

When starting radiusd, you can turn on debug output and set the level of output with the -x option. Each instance of the -x option at the command line will increase the debug level by one up to level 4. After the server is started, you continue to control the level of debugging output with the radsignal command. Each debug level provides the information from the previous levels, plus its own. The higher the number, the more detail.

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No debugging (default)</td>
</tr>
<tr>
<td>1</td>
<td>Brief trace</td>

</tr>
<tr>
<td>3</td>
<td>Full function tracing</td>
</tr>
<tr>
<td>4</td>
<td>Low-level FSM and configuration file output</td>
</tr>
</tbody>
</table>

**DESCRIPTION** roll logfile

This form of invocation specifies that you wish radiusd to immediately roll the logfile. “rolling” the logfile consists of closing the current logfile and opening a new logfile. If, for example, the current logfile is named 'logfile.20130209' then it will be renamed to 'logfile_part01.20130209' and the current logfile will be called 'logfile_part02.20130209'. This is the same as what is done if the logfile reaches the maximum configured file size. Each subsequent request to roll the logfile will increment the 2-digit “part number” up to a maximum of 99 and will grow to 3-digit or larger “part numbers” as required.

The file name modification algorithm is to insert “_partNN” into the filename preceding the last dot of the file name. The intent is to preserve the filename extension, in case the filename extension is used by the server administrator.

**DESCRIPTION** roll stream

This form of invocation specifies that you wish radiusd to immediately roll the accounting stream specified by <stream-name>. “rolling” the accounting stream consists of closing the current file used for that stream and opening a new file for the stream. If, for example, the current
accounting logfile for the stream is named 'session.2013-02-09.log' then it will be renamed to 'session.2013-02-09_part01.log' and the current accounting logfile will be called 'session.2013-02-09_part02.log'. This is the same as what is done if the accounting logfile reaches the maximum configured file size. Each subsequent request to roll the accounting stream will increment the 2-digit “part number” up to a maximum of 99 and will grow to 3-digit or larger “part numbers” as required.

The file name modification algorithm is the same as roll logfile above.
**radrecord**

The **radrecord** utility reads Interlink (MERIT-style) accounting log files and prints out specific accounting record information to standard output. This utility will not read Livingston Call Detail Records. Using various command line options, it is possible to create flexible and powerful search criteria to obtain information from the logs.

The accounting information that is displayed includes:

- The user name
- The total session time
- The number of records
- The average time per session

**Note:** If any accounting log file is compressed with either gzip (1) or compress (1), **radrecord** will try to use the corresponding decompression program to read the file.

You can also read the accounting logs through the Server Manager Accounting page.

**Synopsis**

```
radrecord -a <After> -b <Before> -d <Directory> -do <Directory>
-f -h -i <Session-ID> -l <Log-config> -n <NAS/port> -o <Time>
-p <Protocol> -r <Reason>:<Reason> -t <Token-pool> -u <User-ID>
-v -x -y <type> -:attribute=value -0
-1 <filename> <Accounting-logfile> <...>
```

**Arguments**

*<Accounting-logfile>* One or more accounting log files to search.

**Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a &lt;After&gt;</td>
<td>Select records for sessions ending after the specified date/time. The date/time string is in the format <code>yyyy-mm-dd/hh:mm:ss</code>. For example, <code>2012-12-01/15:01:30</code> means 3:01:30pm, December 1, 2012. Hour, minute, and second may be omitted and each default to 0.</td>
</tr>
<tr>
<td>-b &lt;Before&gt;</td>
<td>Select records for sessions ending before the specified date/time. The date/time string is in the format <code>yyyy-mm-dd/hh:mm:ss</code>. For example, <code>2013-02-01/15:01:30</code> means 3:01:30pm, February 1, 2013. Hour, minute, and second may be omitted and each default to 0.</td>
</tr>
</tbody>
</table>
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-d &lt;Directory&gt;</code></td>
<td>The directory containing the RAD-Series Server dictionary, vendors, and log.config files, instead of the default /etc/opt/aaa directory. If no <code>-d</code> option is given, radrecord will look in the default location. An error will be displayed if the configuration files cannot be found.</td>
</tr>
<tr>
<td><code>-f</code></td>
<td>Verbose output.</td>
</tr>
<tr>
<td><code>-h</code></td>
<td>Displays the radrecord syntax.</td>
</tr>
<tr>
<td><code>-i &lt;Session-ID&gt;</code></td>
<td>Only searches for records with the given session ID.</td>
</tr>
<tr>
<td><code>-l &lt;Log-config&gt;</code></td>
<td>Outputs any selected records in the specified format and to the file configured in the specified configuration file for the LOG AATV (defaults to log.config).</td>
</tr>
<tr>
<td><code>-n &lt;NAS/port&gt;</code></td>
<td>Only searches for records with the given NAS ID and (optionally) port.</td>
</tr>
<tr>
<td><code>-o &lt;Time&gt;</code></td>
<td>Select only records for sessions ongoing at the specified date/time. The date/time string is in the format <code>yyyy-mm-dd/hh:mm:ss</code>, e.g., 2012-07-26/12:49:03. Hour, minute, and second may be omitted, and each default to 0.</td>
</tr>
<tr>
<td><code>-p &lt;Protocol&gt;</code></td>
<td>Only searches for records that used the specified protocol.</td>
</tr>
<tr>
<td><code>-r &lt;Reason&gt;:&lt;Reason&gt;</code></td>
<td>Only searches for accounting records with a reason code within the specified range. A reason code may either be a integer or a text name, as listed in the Session-State value section of the dictionary file, e.g., <code>-r 2</code> or <code>-r 2:3</code> or <code>-r COLLISION</code> or <code>-r ACTIVE:FINISHED</code></td>
</tr>
<tr>
<td><code>-t &lt;Token-pool&gt;</code></td>
<td>Only searches for records that used a token from a token pool matching the specified regular expression.</td>
</tr>
<tr>
<td><code>-u &lt;User-ID&gt;</code></td>
<td>Only searches for records that match the user ID regular expression.</td>
</tr>
<tr>
<td><code>-v</code></td>
<td>Display version of radrecord.</td>
</tr>
<tr>
<td><code>-x</code></td>
<td>Add to debug flag value. May occur 0 to 4 times. Each additional <code>-x</code> will increase the amount of debug output.</td>
</tr>
<tr>
<td><code>-y &lt;Service-Type&gt;</code></td>
<td>Only searches for records with a service type name matching the specified service type regular expression.</td>
</tr>
<tr>
<td><code>--attribute=value</code></td>
<td>Specify an A-V pair to match with each accounting record. This may be used multiple times if needed.</td>
</tr>
<tr>
<td><code>-0</code></td>
<td>Suppress copyright message in the output.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-1 &lt;filename&gt;</td>
<td>Find only first record of each user listed in the specified file. You must create and save the file with a list of users.</td>
</tr>
</tbody>
</table>
sesstab

The sesstab utility reads binary session.las files and prints out specific session information to standard output. Using various command line options, it is possible to create flexible and powerful search criteria to obtain information from the session.las file. Note that options -a, -i, -n, -p, -r, and -s can be repeated to add additional criteria. For example, “-a fred@co.com -a joe@bp.com” will report sessions for both users.

The information for each selected session is, by default, printed one line per user:

<Access-Id> <State> <Session-Id> <NAS-Identifier> <NAS-Port> <Token-Name> <Date> <Start-Time> <Connect-Time>

<Access-Id> is the Authenticated-User-Name i.e usually the User-Name but can be the Inner-Identity for tunneled users.

You can also view session information through the Server Manager Sessions page.

Note: The session.las file is a binary snapshot of the sessions currently tracked by the RAD-Series Server. Completed sessions remain in session.las for another 45 seconds by default and are therefore available for sesstab to report on. The session.las file is updated every 5 minutes by default. See the "-writesess" option of "radcheck" on page 110, “las.conf” on page 238 and “Session Table Update Interval” on page 80 for ways to change this interval.

Synopsis

sesstab  -a <username>  -d <config_dir>  -dd <sess_dir>  -f  -f  -h
          -i <userid>  -n <nasid>  -p <port>  -r <realm>  -s <state>
          -t <Token-pool>  -v  -0 <file> <file> <...>

Arguments

<file> One or more files that may be used as an alternate to the session.las file.

Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a &lt;username&gt;</td>
<td>Select only sessions with specified user name(s) in &quot;name@realm&quot; format.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-d &lt;config_dir&gt;</td>
<td>The directory containing the RAD-Series Server dictionary and vendors files. If no -d option is given, sesstab will look first for a directory ../aaa and if none is found, use the default /etc/opt/aaa location. An error will be displayed if neither directory can be used to locate the various server configuration files.</td>
</tr>
<tr>
<td>-dd &lt;sess_dir&gt;</td>
<td>Directory where the session file(s) are located. The default is '/var/opt/aaa/data'.</td>
</tr>
<tr>
<td>-f</td>
<td>Display sessions in detailed (multi-line) format.</td>
</tr>
<tr>
<td>-f -f</td>
<td>Display sessions in detailed (multi-line) format, plus attributes from last saved accounting message.</td>
</tr>
<tr>

<td>Select only sessions connecting from the specified realm(s).</td>
</tr>
<tr>
<td>-s &lt;state&gt;</td>
<td>Select only sessions with the specified session state(s).</td>
</tr>
<tr>
<td>-t &lt;Token-pool&gt;</td>
<td>Select only sessions with tokens from the specified pool.</td>
</tr>
<tr>
<td>-v</td>
<td>Display version of sesstab.</td>
</tr>
<tr>
<td>-0</td>
<td>Suppress copyright message in the output.</td>
</tr>
</tbody>
</table>
Troubleshooting

Debugging

The RAD-Series Server can be set to print out debugging information that may be useful for troubleshooting. The debug level and directory is set when the server is started. See “Setting Server Start Options” on page 33 and “radsignal” on page 115 to change the debug level.

All debug output is sent to the `radius.debug` file in the server log file directory.

Error Messages

Below are error messages that may be helpful for troubleshooting.

Server Log File Messages

These messages appear in the server’s log file.

<table>
<thead>
<tr>
<th>Message</th>
<th>Probable Cause</th>
<th>Possible Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request from unknown client.</td>
<td>Using DNS names, rather than IP addresses, to specify clients. Upon startup, entries in your clients file are not yet in the server’s buffer, so this message may appear at the beginning of the server log file. It only indicates a problem if the server continues to fail to resolve DNS names.</td>
<td>Enter correct DNS name in clients file entry. Add both backward and forward entries for client in DNS database.</td>
</tr>
<tr>
<td>LAS_ACCT: user realm 'xxx.xxx' not configured</td>
<td>Realm is not configured in the las.conf file and you’re using the LAS feature for authorization policies.</td>
<td>Add the realm to the las.conf file.</td>
</tr>
<tr>
<td>read_clients: Missing required client 'xxx': line y</td>
<td>Entry on line y of the clients file is missing the required parameter 'xxx'.</td>
<td>Add the omitted parameter to the clients file entry.</td>
</tr>
<tr>
<td>Couldn’t get our own IPv4 address. ourhostname('XXX')</td>
<td>No entry for the RAD-Series Server in your DNS database or / etc/hosts.</td>
<td>Add both backward and forward entries for RAD-Series Server in DNS database or add the host name to /etc/hosts.</td>
</tr>
</tbody>
</table>
### radiusd Error Messages

These messages are returned by the RAD-Series Server if `radiusd` fails to start. They appear in the Message frame at the bottom of the Server Manager Administration page or on your terminal screen.

<table>
<thead>
<tr>
<th>Message</th>
<th>Probable Cause</th>
<th>Possible Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>doconfig: init_fsm() failed</td>
<td>Finite state machine failed to initialize.</td>
<td>Verify that radius.fsm exists in the server configuration file directory. If you modified the .fsm, be sure all entries follow the correct syntax.</td>
</tr>
<tr>
<td>init_fsm: FSM defined with -x states from radius.fsm</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file_pass: password failure for 'xxx'</td>
<td>User provided an incorrect password</td>
<td>Verify password with user. Add correct password to .users file or user profile database.</td>
</tr>
<tr>
<td>readSessionTable: Session checkpoint file '/var/opt/aaa/data/session.las' is too old, ignored.</td>
<td>The server has been down for an extended period or his clock is wrong</td>
<td>Check to make sure his clock is correct.</td>
</tr>
<tr>
<td>Vendor-specific attribute contains unknown vendor code: y</td>
<td>Server received an attribute for a vendor that is not defined in the vendor file.</td>
<td>Add vendor to the vendor file.</td>
</tr>
<tr>
<td>Discarding unknown received attribute: Vendor x attribute y</td>
<td>Server received an attribute that is not defined in the dictionary.</td>
<td>Add vendor-specific attributes to the dictionary file.</td>
</tr>
</tbody>
</table>

### Message Probable Cause Possible Solution

<table>
<thead>
<tr>
<th>Message</th>
<th>Probable Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invalid auth port number</td>
<td>Authentication port number is a non-numerical value or out of range</td>
<td>Specify a numerical value in Start Options.</td>
</tr>
<tr>
<td>Invalid acct port number</td>
<td>Accounting port number is a non-numerical value or out of range</td>
<td>Specify a numerical value in Start Options.</td>
</tr>
<tr>
<td>Invalid option option</td>
<td>The named option is invalid.</td>
<td>Review the options in your configuration file entries. See Chapter 5 for a list of valid options.</td>
</tr>
<tr>
<td>Couldn't open path/logfile.yyyymmdd for logging, error 2 No such file or directory</td>
<td>The directory specified for the logfile does not exist.</td>
<td>Create the directory or specify the correct server log file directory in Server Connections.</td>
</tr>
</tbody>
</table>
### Server Reply Messages

These messages may be sent to users when access has been rejected.

<table>
<thead>
<tr>
<th>Message</th>
<th>Probable Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Couldn’t open path/logfile.yyyymmdd for logging, error 13 Permission denied</td>
<td>radiusd does not have write permission for the directory.</td>
<td>Change permissions of directory or specify an alternate server log file directory in Server Connections.</td>
</tr>
<tr>
<td>bind: Address already in use</td>
<td>Another process is already using the port.</td>
<td>Kill the process or change the port number used by radiusd. The port is specified in Start Options.</td>
</tr>
<tr>
<td>Cannot resolve client name 'nas'</td>
<td>NAS’s DNS entry is configured incorrectly or not configured at all.</td>
<td>Check DNS configurations for both forward and reverse entries.</td>
</tr>
<tr>
<td>Received invalid reply digest from server</td>
<td>Server and client do not agree on shared secret.</td>
<td>Verify that the shared secret in the clients file agrees with the secret configured on the client.</td>
</tr>
</tbody>
</table>

---

**Interlink Networks, LLC.**
<table>
<thead>
<tr>
<th>Message</th>
<th>Probable Cause</th>
<th>Possible Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Improper ‘userid@realm’ specification</td>
<td>User access ID should be in the format of userid@realm. Most probably, a user has omitted @realm from their logon name and the server has not been configured to handle a NULL realm.</td>
<td></td>
</tr>
<tr>
<td>Invalid authentication realm</td>
<td>The realm identified in the user access ID has not been configured for the server.</td>
<td>Verify that the authfile has an entry for the realm and that radiusd is loading configuration files from the correct location.</td>
</tr>
</tbody>
</table>

Using External Data Stores

The RAD-Series Server allows you to store user profiles in a local realm file or to retrieve them from external data stores. This section shows how to configure the server to access user profiles from:

- LDAP directory servers
- Oracle databases

Using an LDAP Server

If you only need to retrieve user IDs and passwords from the LDAP server, just follow the procedure “Identifying LDAP Directories” on page 55.

However, if you wish to implement simple authorization policies with check or reply items, we recommend that you review this entire topic. It will familiarize you with:

- Interlink-specific attributes and object classes
- Extending the standard LDAP schema

About ProLDAP™

ProLDAP™ is Interlink Networks’ proprietary LDAP schema, based on the OpenLDAP 2.x release. It interfaces with any LDAP server using protocol version 3. Previous OpenLDAP releases are protocol version 2 and are not supported by the currently distributed Interlink Networks schema files.

To determine the version of the LDAP standard used by a commercially released LDAP server, consult the product documentation or contact the vendor. If your LDAP vendor has extended or otherwise modified the version 3 LDAP standard, you may need to modify the ProLDAP schema.

The standard schema file is `iaaa-radius.ldif`. We also include the `55iaaa-radius.ldif` file to extend the schema for Sun Java System Directory Server (formerly called iPlanet).

**Note:** There may be several schema files installed with an LDAP server. Modifying schema files can result in problems. Never delete unused schema elements from the standard schema. They require no additional operational or administrative overhead and deleting them could cause problems.
Securing LDAP Communications

To use Secure Socket Layer (SSL) when communicating with LDAP directories:

**Note:** SSL secures the connection to a specific host and logical port, so repeat this procedure for each directory separately.

1. Follow the steps in Modifying a Directory Configuration to display the LDAP Directory dialog.
2. Click Yes to Use SSL, then click Save.
3. Click Modify.
5. Enter the path to the RAD-Series Server TLS CA certificate directory.
   or
   Enter the name of the RAD-Series Server TLS CA certificate file.
6. Enter the TLS certificate file if required by the LDAP server.
7. Enter the TLS private key file if required by the LDAP server.
8. Click Modify.
9. If the RAD-Series Server is already running:
   • Click Save Configuration and select the RAD-Series Server.
   • Stop and restart the RAD-Series Server.

The RAD-Series Server uses OpenSSL, which requires a random number generator that has been seeded with at least 128 bits of randomness. If there is no default seeding file or if the file is too short, the “PRNG not seeded” error message may occur. To avoid this, use an operating system with the randomness devices:

- `/dev/urandom`
- `/dev/random`

Starting with Solaris 9 these devices are included by default.

On **systems without** `/dev/urandom` or `/dev/random`, it’s a good idea to use the Entropy Gathering Demon (EGD). OpenSSL will automatically look for an EGD socket at `/var/run/egd-pool`, `/dev/egd-pool`, `/etc/egd-pool` and `/etc/entropy`.

Failing that, set the environmental variable RANDFILE to point to the default random seed file:

`/etc/opt/aaa/security/random.rnd`
Password Encryption

The RAD-Series Server can receive passwords from the LDAP server in clear text format or encrypted by SSHA, MD5, SHA1, x-NT hash, x-lm hash and UNIX-crypt. If passwords are encrypted by other methods, configure the RAD-Series Server to bind to the LDAP server for authentication.
Extending the ProLDAP Schema

Do the following if you are storing check and reply items with user profiles in the LDAP directory.

If you are only storing user profiles based on the core LDAP schema (to retrieve the uid and password), this procedure is not necessary.

1. Copy the `iaaa-radius.schema` file to the LDAP server.
2. Modify `slapd.conf` by adding the following line:
   ```
   include Path-to-radiusschemafile
   ```
   Where `Path-to-radiusschemafile` is the full path to location of the `iaaa-radius.schema` file.
3. Add the Interlink-specific attributes to your LDAP user profiles. (See `aaasample.ldif` file for examples.)

If your LDAP server vendor has modified or extended the standard version 3 schema, the `iaaa-radius.schema` file may not work. In this case you will have to modify `iaaa-radius.schema`. The RAD-Series Server includes the `55iaaa-radius ldif` file as an example of a file that has been modified for the Sun Java System Directory Server (formerly called iPlanet) LDAP server.

Interlink Object Classes

The extended schema files contain the Interlink object class:

<table>
<thead>
<tr>
<th>Object Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aaaPerson</td>
<td>Represents the set of attributes a user entry must or may contain.</td>
</tr>
</tbody>
</table>

Interlink-specific Attribute Types

The following Interlink attributes are used to store check/reply items.

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aaaCheck</td>
<td>An A-V pair that must be present in the user entry for the entry to evaluate to True</td>
</tr>
<tr>
<td>aaaDeny</td>
<td>An A-V pair that must not be present in the user entry for the entry to evaluate to True</td>
</tr>
<tr>
<td>aaaReply</td>
<td>An A-V pair sent back to the access device to authorize the session (e.g. to set a session time limit)</td>
</tr>
</tbody>
</table>
**LDIF User Entry Syntax**

User entries must contain any attribute-value pairs required by the `aaaPerson` object class or whichever alternate object class you specify for the `ObjectClass` parameter.

In an LDIF file, a user entry is represented as follows:

```

dn:  attr = value, attr = value,...
ObjectClass:  aaaPerson
uid:  value
userPassword:  value
User-ID:  value
User-Password:  value
aaaCheck:  attr = value
aaaDeny:  attr = value
aaaReply:  attr = value
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dn</td>
<td>Distinguished Name. Identifies a directory entry in the LDAP schema by using a series of comma-separated attributes and values, where the left-most value specifies the actual directory object and the right-most value specifies the directory root point. For example, ou=people, o=interlink.com points to the organizational unit, people, located on the directory branch below the organization, interlink.com.</td>
</tr>
<tr>
<td>uid</td>
<td>User identifier. Normally, uid or cn is part of dn. This is the default filter for a realm. If you specify another attribute as the filter, this parameter is optional.</td>
</tr>
<tr>
<td>userPassword</td>
<td>LDAP attribute that identifies the password for the user.</td>
</tr>
<tr>
<td>ObjectClass</td>
<td>Indicates what A-V pairs must or may be used in the user entry. This attribute is not required for user authentication, but it is required if you wish to add User-ID, User-Password, Check/Deny, or Reply Items to the user profile. In addition to or instead of <code>aaaPerson</code>, other object classes (e.g., the standard LDAP schema Person class) may be specified.</td>
</tr>
<tr>
<td>User-ID</td>
<td>RADIUS attribute that may be used to identify a user (instead of uid).</td>
</tr>
<tr>
<td>User-Password</td>
<td>RADIUS attribute, defined in the <code>aaaPerson</code> object class.</td>
</tr>
<tr>
<td>aaaCheck, aaaDeny, aaaReply</td>
<td>Specify any A-V pair(s) defined in the RAD-Series Server's dictionary file that you wish to use as a check, deny, or reply item for the user.</td>
</tr>
</tbody>
</table>
Check and Reply Items

The ProLDAP implementation lets you store check and reply items with user profiles.

If your RAD-Series Server implementation includes user check or reply items, configure these items to be returnable in a search of the LDAP directory. Binding as the user will not return check items.

To Override Simultaneous Session Limit

This A-V pair overrides the global simultaneous session limit set in Server Properties.

```
aaaCheck: Simultaneous-Use = Max-number-sessions
```

To Control Access Points

These A-V pairs specify the NAS port or machine through which the user is permitted to access the network.

```
aaaCheck: NAS-Port = Port-number
aaaCheck: NAS-ID = ID-string
aaaCheck: Calling-Station-ID = User-MAC-address
```

To Deny Access

These A-V pairs deny the user access from the port or machine specified.

```
aaaDeny: NAS-Port = Port-number
aaaDeny: NAS-ID = value
aaaDeny: Called-Station-ID = AP-MAC-Address
```

To Set Reauthentication Session Timeout

```
aaaReply: Session-Timeout = Number-seconds
aaaReply: Termination-Action = 1
```

To Set Idle Timeout

```
aaaReply: Idle-Timeout = Number-seconds
```

To Assign Static IP Address

This A-V pair cannot be used with an 802.1X framework.

```
aaaReply: Framed-IP-Address = value
```

To Apply Filters

```
aaaReply: Filter-ID = value
```
Known Issues with ProLDAP™

These are a few issues to be aware of when configuring the RAD-Series Server to use ProLDAP.

Failover not operating properly

If the LDAP server process terminates in such a way that the TCP connection remains active, the RAD-Series Server will not recognize that the LDAP server is not accessible. Instead of rotating to the next LDAP server, the RAD-Series Server will retransmit the request until it times out.

Authentications time out on LDAP restart

If the LDAP server is started (or restarted) while the RAD-Series Server is running, one or two authentication requests may timeout during the LDAP restart. Starting the LDAP server before starting the RAD-Series Server will prevent this issue from occurring.

Case-sensitive Filter IDs

A feature of LDAP servers is that they match Distinguished Names in a case-insensitive manner. Using case-sensitive filter IDs could cause Distinguished Names to be mismatched or not found.

Clear-text passwords stored in LDAP

The regular expression `^{.+}.*$` indicates that the password is hashed using the scheme named between the `{` and `}` characters. There is no specification for handling clear-text (unhashed) passwords that contain a leading prefix of `{.+}`. This leads to confusions, such as:

- `{md5}` looks like hasher ‘md5’ produced a zero-length hash
- `{nothing}interesting` looks like hasher ‘nothing’ produced a hash of ‘interesting’

Any clear-text password that appears to be hashed will be rejected as invalid by the Interlink RAD-Series Server. Most likely, the apparent hasher will be rejected as invalid. Even if the apparent hasher is valid, the apparent hash will be invalid. Therefore, a user could supply the correct password, only to have the server reject it as invalid. It should be noted that the LDAP standard already recommends against storing clear-text passwords in an LDAP directory.

Lost LDAP-Response Messages

If the LDAP server is installed on the same host as the RAD-Series Server or if it is an especially fast LDAP server, some of the LDAP-response messages may be lost by the RAD-Series Server and authentication requests will timeout.
Using Oracle® Database

The AAA Oracle module allows you to retrieve user profiles from an Oracle database. When dealing with a large number of users, an Oracle data store delivers much higher server performance than File or Unix-PW storage. It also supports the server’s load balancing feature.

Oracle can be configured to store:

- User name and password
- A limited set of reply item attributes

Its current limitations are:

- No check or deny item attributes
- No logging of Accounting-Requests to database, only to text file

You can store users in an Oracle database on one platform and authenticate those users with a RAD-Series Server installed on another platform, such as the Red Hat Linux operating system.

To set up realms to use an Oracle data store, follow the procedure “Identifying Oracle Servers” on page 58.

Requirements

To implement an Oracle data store, you must first purchase and install:

- Red Hat Enterprise Linux or Sun Solaris operating systems. Only these platforms support the db_srv daemon required to communicate with Oracle.
- Oracle development package. This includes the libraries required by the db_srv daemon.

Set up your environment to enable the Oracle database and db_srv daemon.

Oracle Data Store Processing

When the RAD-Series Server receives a request from a user in a realm that has been configured for Oracle storage, the Finite State Machine (FSM) calls the iaaaRealm action, which in turn calls the Oracle action to retrieve user profiles from the Oracle database.

When the Oracle action receives a request from iaaaRealm, it uses the AUTH_NET_REQ data structure to send the request to the db_srv daemon. The daemon acts as an Oracle listener, waiting to receive requests from the Oracle action. db_srv daemon sends a SQL query to the Oracle database and uses the AUTH_NET_USERSAUTH_NET_USER data structure to return the appropriate replies to the Oracle action. The Oracle action returns the results to the FSM.

Multiple db_srv daemons can communicate with a single database or a set of replicated databases. Each daemon must be on a different machine or listening to a different port.
The Oracle module also provides round-robin load balancing and failover of Oracle db_srv daemons.

**Storing User Profiles in Oracle**

The RAD-Series Server authenticates users against the values stored in the `network_auth_name` and `network_auth_password` columns of the `AUTH_NET_USERS` table. The rest of the table stores RADIUS reply items returned to the RAD-Series Server through the `db_srv` daemon.

**Users Table Structure**

Define a users table with the following SQL statements:

```sql
create table AUTH_NET_USERS

(network_auth_name VARCHAR2(63),
 network_auth_password VARCHAR2(128),
 session_timeout number (10),
 idle_timeout number(10),
 port_limit number(10),
 tunnel_type number(10),
 tunnel_medium_type number(10),
 tunnel_client_end VARCHAR2(64),
 tunnel_server_end VARCHAR2(64),
 acct_tunnel_connection VARCHAR2(64),
 service_type number(10),
 framed_protocol number(10),
 framed_ip_addr number(10),
 framed_ip_netmask number(10),
 framed_routing number(10),
 filter_id VARCHAR(128),
 framed_compression number(10)
);

COMMIT;
```
The columns in the `AUTH_NET_USERS` table correspond to the following RADIUS attributes. Store the A-V pair value in the corresponding column.

<table>
<thead>
<tr>
<th>Column</th>
<th>RADIUS Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>network_auth_name</code></td>
<td>User-Name</td>
</tr>
<tr>
<td><code>network_auth_password</code></td>
<td>Password</td>
</tr>
<tr>
<td><code>network_timeout</code></td>
<td>Session-Timeout</td>
</tr>
<tr>
<td><code>idle_timeout</code></td>
<td>Idle-Timeout</td>
</tr>
<tr>
<td><code>port_limit</code></td>
<td>Port-Limit</td>
</tr>
<tr>
<td><code>tunnel_type</code></td>
<td>Tunnel-Type</td>
</tr>
<tr>
<td><code>tunnel_medium_type</code></td>
<td>Tunnel-Medium-Type</td>
</tr>
<tr>
<td><code>tunnel_client_end</code></td>
<td>Tunnel-Client-End</td>
</tr>
<tr>
<td><code>tunnel_server_end</code></td>
<td>Tunnel-Server-End</td>
</tr>
<tr>
<td><code>connection_id</code></td>
<td>Connection-Id</td>
</tr>
<tr>
<td><code>service_type</code></td>
<td>Service-Type</td>
</tr>
<tr>
<td><code>framed_protocol</code></td>
<td>Framed-Protocol</td>
</tr>
<tr>
<td><code>framed_ip_address</code></td>
<td>Framed-IP-Address</td>
</tr>
<tr>
<td><code>framed_ip_netmask</code></td>
<td>Framed-IP-Netmask</td>
</tr>
<tr>
<td><code>framed_routing</code></td>
<td>Framed-Routing</td>
</tr>
<tr>
<td><code>filter_id</code></td>
<td>Filter-Id</td>
</tr>
<tr>
<td><code>framed_compression</code></td>
<td>Framed-Compression</td>
</tr>
</tbody>
</table>
**Create the Users Table**

To execute the table statement:

1. Start an instance of the database where user profiles will be stored.
2. Start SQL*Plus and connect to the database.
3. At the SQL prompt, enter `START create.sql` to create the users table.
4. Add user records to the table with the following SQL command:
   ```sql
   insert into AUTH_NET_USERS values ('User-Name', 'Password', Session-Timeout, Idle-Timeout, Port-Limit, Tunnel-Type, 'Tunnel-Client-End', 'Tunnel-Server-End', 'Acct-Tunnel-Connection', Service-Type, Framed-Protocol, Framed-IP-Address, Framed-IP-Netmask, Framed-Routing, 'Filter-Id', Framed-Compression);
   commit;
   ```
   Replace the variables in the example above with the attribute values for this user. Enclose string type values in quotes. You can write a NULL value to any attribute, except for **User-Name** and **Password**.

**Note:** You can add all users at once by modifying the fill.sql command file included with db_srv, then running `START fill.sql` from the SQL prompt.

Always create the table:
- In the database’s default SYSTEM table space
- In the default database or a database that has been assigned an SID

**Modify the Users Table**

To remove users from the table, at the SQL prompt, enter:
```sql
delete * from AUTH_NET_USERS where network_auth_name = 'User-Name';
commit;
```
Substitute the `network_auth_name` column value for the ‘User-Name’ placeholder.

**Note:** You can use the clear.sql command file included with db_srv to clear all users from the table. Run `START clear.sql` from the SQL prompt.

Whenever modifying the SQL statement or `create.sql` script that creates the users table:
- Always name the table `AUTH_NET_USERS`
- Do not add, remove, modify, or change the order of the predefined columns
Configuring db_srv Daemon

The db_srv daemon is the client that interfaces with the Oracle database and RAD-Series Server. Run a daemon on each Oracle database host machine you wish to access (one db_srv per AAA connection).

Install db_srv Daemon

The db_srv Daemon is installed with the RAD-Series Server. If the Oracle database is also hosted on this machine, you can choose Oracle server as a component when you install the RAD-Series Server software. If not, run the installer on the machine that hosts the Oracle database and choose to install only the Oracle server component.

To install the daemon:

1. Copy the AAA installer from the download directory to the Oracle host machine.
2. Log on as the user permitted to communicate with the Oracle database.
3. Run the installer:
   ```bash
   # sh /local directory path/RAD-Series.8.1.0.solaris.sun4u.bin
   ```
4. Enter option number 4 for Oracle:
   ```bash
   ENTER A COMMA-SEPARATED LIST OF NUMBERS REPRESENTING THE COMPONENTS TO BE INSTALLED: 4
   ```
5. Follow the prompts to choose the directories where you want the files installed.

Edit db_srv.opt

Before executing the daemon, edit the configuration file, db_srv.opt (in /etc/opt/aaa by default):

1. Locate the lines:
   ```bash
   DB_SRV_PORT=Port
   DB_SRV_ORA_UID=User-Name
   DB_SRV_ORA_PWD=Password
   DB_SRV_ORA_SID=Oracle-SID
   export DB_SRV_PORT DB_SRV_ORA_UID DB_SRV_ORA_PWD DB_SRV_ORA_SID
   ```
2 Enter values for:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB_SRV_PORT</td>
<td>Port number used by db_srv for incoming authentication requests from the RAD-Series Server. Should match port you configure on the RAD-Series Server. Any available port number may be used. Typically, port numbers greater than 4000 are used, since port numbers for standard services are usually less than 4000. If multiple db_srv daemons are running on the same machine, each daemon must be listening to a different port.</td>
</tr>
<tr>
<td>DB_SRV_ORA_UID</td>
<td>Oracle user name used to access the database.</td>
</tr>
<tr>
<td>DB_SRV_ORA_PWD</td>
<td>Oracle password used to access the database.</td>
</tr>
<tr>
<td>DB_SRV_ORA_SID</td>
<td>Oracle ID for the database to connect to when more than one database exists on the machine. If the parameter is omitted, the daemon connects to the default database, which is defined during database installation.</td>
</tr>
</tbody>
</table>

**Start db_ser Daemon**

To execute the daemon, at the command line, run:

```bash
run_db_srv.sh
```

If `db_srv.opt` is not installed in the default location, use the `-f Directory` option where `Directory` is the full path to the configuration file.
Using Advanced Policy

The RAD-Series Server Advanced Policy module lets you define advanced policies to control the processing of requests. Advanced policies are logical expressions that result in a true or false answer when evaluated against a request. Depending on the outcome, A-V pairs may be added to the request as reply items and event codes may be returned to the FSM to control progress to the next state.

Unlike the user check and deny items, advanced policies can include a wide range of criteria and comparisons using:

- Boolean operators and relative operators
- Complex expressions
- Nested statements

Advanced policies are specifically used to implement:

- Dialed Number Identification Service (DNIS) routing
- Dynamic Access Control (DAC) time-based provisioning
- Control access according to NAS addresses or ports
- Logical user groups (other than realm)

Decision Files

Advanced policies are defined in decision files. The older format contains policy group entries which are still supported but it is not documented here. If you are using the group format you can refer to your old documentation. The new format is more of a scripting language and should be easier to use. The Decision file must be all the same format, the formats can not be intermixed.

Decision files make policy decisions by matching requests to a sequence of conditions. The Decision file is evaluated against the request removing, modifying and/or adding A-V pairs as directed until an `exit` command is encountered. Any remaining lines are not evaluated. The `exit` command specifies the state machine event to give the state machine. The event is used to control the flow through the state machine. For instance, the NAK event will cause the state machine to send a NAK to the request. See “Finite State Machine (FSM)” on page 256 for more information on FSMs.
Implementing Advanced Policies

The default FSM file distributed with the RAD-Series Server provides several places to implement advanced policies:
1. Request pre-processing policy
2. User/Realm policy
3. Reply post-processing policy
4. Proxy send request policy
5. Proxy receive response policy

The `radius.fsm` file can also be modified to implement advanced policies in decision files at additional points in the FSM file. See “Calling Decision Files” on page 187 for further details on modifying the FSM file to implement advanced policies.

Request pre-processing policy

All requests are subjected to the request pre-processing policy that is defined in the `request-ingress.grp` decision file. The request pre-processing policy is applied as the very first step in the FSM, before the request is dispatched for processing.

The request pre-processing policy may alter the request arbitrarily:
- A-V pairs may be added, changed, or removed
- The request classification may be altered
- The request may be rejected immediately
- The request may be dropped entirely, there will be no reply sent
Flow of Request Pre-Processing Policy
**User/Realm policy**

All requests are subjected to user/realm policy after authentication. User/realm policy is applied only after a successful authentication.

A user policy is specified in a `Policy-Pointer` attribute on the request as either a check item or a reply item, see “Policy-Pointer” on page 70 for information on configuring it. If the `Policy-Pointer` attribute is found in the check items then the Server will not look for one in the reply items. The value of the `Policy-Pointer` attribute is treated just like the Xstring value from the FSM file; it specifies the URL for the decision file to be evaluated.

A realm policy is specified in a `Policy-Pointer` parameter in a ProLDAP realm entry in an authfile. The value of the `Policy-Pointer` parameter is treated just like the Xstring value from the FSM file; it specifies the URL for the decision file to be evaluated.

If a request contains a `Policy-Pointer` attribute, as either a check item or a reply item, the named advanced policy will be applied. If a request contains no `Policy-Pointer` attribute and the realm entry has a `Policy-Pointer` parameter, the named advanced policy will be evaluated. If neither the request, nor the realm entry, contain a `Policy-Pointer`, then no user or realm policy is applied; in this case the POLICY action returns an ACK event to the FSM.

See the “Authorization flow in default Finite State Machine” on page 9 for the flow of user/realm policy.

**Reply post-processing policy**

All replies are subjected to the reply post-processing policy that is defined in the `reply-egress.grp` decision file. The reply post-processing policy is applied as the very last step in the FSM, just before the RADIUS reply message is created and sent.

The reply post-processing policy may alter the request arbitrarily:

- A-V pairs may be added, modified, or removed
- The reply type may be changed
- The request may be dropped entirely, there will be no reply sent

If the client is defined as `type=NAS` or `type=PROXY+PRUNE` (possibly including vendors), the pruning rules specified in the dictionary will have been applied according to the reply type that was in effect before the post-processing policy is evaluated.
Flow of Reply Post-Processing Policy
Proxy send request policy

All requests that need to be proxied are subjected to the proxy send request policy defined in the proxy-egress.grp decision file. The proxy send request policy is applied as the very last step in the FSM before the RADIUS proxy request message is created and sent.

The proxy send request policy may alter the request arbitrarily except as noted below:
- A-V pairs may be added, modified, or removed
- The request may be rejected immediately
- The request may be dropped entirely, there will be no reply sent
- The proxy target host may be changed

**Note:** Do NOT modify or remove any Proxy-State or Proxy-Action A-V pairs. Doing so will interfere with proxy functionality.

*Flow of Proxy Send Request Policy*
**Proxy receive response policy**

All proxy replies are subjected to the proxy receive response policy defined in the proxy-ingress.grp decision file. The proxy receive response policy is applied as the very first step in the FSM after the reply is received.

The proxy receive response policy may alter the request arbitrarily:
- A-V pairs may be added, modified, or removed
- The reply type may be altered
- The request may be rejected immediately
- The request may be dropped entirely, there will be no reply sent

*Flow of Proxy Receive Response Policy*
Policy Syntax

There are several action command keywords:

- if ( <bool-expr> ) { <action-list1> } else { <action-list2> }
- delete <attr-spec>
- insert <attr-spec> = <value-expr>
- modify <attr-spec> = <value-spec>
- exit "<event-name>"
- log "<log-level>" "<log-message>", <attr-spec>, ...

Keywords and function names are case-sensitive.

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>if</td>
<td><code>&lt;bool-expr&gt;</code> is a boolean expression. See &quot;Boolean Expressions&quot; on page 166 for a description. <code>&lt;action-list1&gt;</code> and <code>&lt;action-list2&gt;</code> are sequences of action commands that may include additional if commands, nested to an arbitrary depth. When the <code>else</code> clause is omitted, <code>&lt;action-list2&gt;</code> may be considered an empty sequence of action commands.</td>
</tr>
<tr>
<td>delete</td>
<td><code>&lt;attr-spec&gt;</code> is an attribute specification. The use of instance specification, including &quot;last&quot; and &quot;*&quot;, is allowed. The use of attribute functions is not permitted</td>
</tr>
<tr>
<td>insert</td>
<td><code>&lt;attr-spec&gt;</code> is an attribute specification. The use of instance specification, including &quot;begin&quot; and &quot;last&quot; is allowed. The use of attribute functions is not allowed. The default instance for <code>&lt;attr-spec&gt;</code> is &quot;last&quot;. <code>&lt;value-expr&gt;</code> is a value expression. <code>&lt;value-expr&gt;</code> may use an attribute specification. The use of instance specification, including &quot;last&quot;, is allowed. The use of attribute functions is allowed. If <code>&lt;value-expr&gt;</code> refers to an attribute, the default instance is &quot;last&quot;. If <code>&lt;value-expr&gt;</code> refers to an instance that is not present, a no-such-instance runtime error occurs. See “Error Handling” on page 184 for details. The types of <code>&lt;attr-spec&gt;</code> and <code>&lt;value-spec&gt;</code> must be compatible. See “Type Compatibility” on page 169 for details.</td>
</tr>
</tbody>
</table>
**modify**  
<attr-spec> is an attribute specification. The use of instance specification, including “last”, is allowed. The use of attribute functions is not allowed. The default instance for <attr-spec> is “last”. If <attr-spec> refers to an instance that is not present, a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.

<value-spec> is a value specification. <value-spec> may use attribute-specifications. The use of instance specification, including “last”, is allowed. The use of attribute functions is allowed. If <value-spec> refers to an attribute, the default instance for <value-spec> is “last”. If <value-spec> refers to an instance that is not present, a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details. The value types for <attr-spec> and <value-spec> must be compatible. See “Type Compatibility” on page 169 for details.

**exit**  
<event-name> must be a quoted string. <event-name> must specify an event that is defined. There are a number of predefined events. Additional events may be defined in the FSM file using “%event <name>” syntax. See “Events” on page 258 for more detailed information on finite state machine events. Event names are case-insensitive (MyEvent is the same as MYEVENT).

**log**  
<log-level> must be a quoted string. <log-level> must be a log-level type: NOTICE, ERROR, CRITICAL, ALERT, WARNING, INFO. <log-level> is case-insensitive (“ERROR” is the same as “Error”). <log-message> must be a quoted string. Multiple instances for <attr-spec> are allowed and cause all named instances to be reported in the logfile. The use of instance specification, including “last” and “*”, is allowed. The default instance specification for the attributes in the log command is “last”. If <attr-spec> refers to an instance that is not present, this will be indicated in the logfile output. A no-such-instance run-time error will NOT be generated in this case.
There are several Attribute Functions:

- `count( <attr-spec> )`
- `length( <attr-spec> )`
- `substr( <attr-spec> ... )`
- `tolower( <attr-spec> )`
- `toupper( <attr-spec> )`

Keywords and function names are case-sensitive.

<table>
<thead>
<tr>
<th>Function</th>
<th>Parameter Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td><code>&lt;attr-spec&gt;</code> is an attribute specification. The use of instance specification, including “last” and “*”, is allowed. The use of an attribute function is not allowed. The default instance for <code>&lt;attr-spec&gt;</code> is “last”.</td>
</tr>
<tr>
<td>length</td>
<td><code>&lt;attr-spec&gt;</code> is an attribute specification. The use of instance specification, including “last”, is allowed. The use of an attribute function is not allowed. The default instance for <code>&lt;attr-spec&gt;</code> is “last”.</td>
</tr>
<tr>
<td>substr</td>
<td><code>&lt;attr-spec&gt;</code> is an attribute specification. The use of instance specification, including “last”, is allowed. The use of an attribute function is not allowed. The default instance for <code>&lt;attr-spec&gt;</code> is “last”. Keywords of “offset”, “before”, “before last”, “after” and “after last” define the rest of the command format. See “substr function” on page 181 for a detailed description.</td>
</tr>
<tr>
<td>tolower</td>
<td><code>&lt;attr-spec&gt;</code> is an attribute specification. The use of instance specification, including “last”, is allowed. The use of an attribute function is not allowed. The default instance for <code>&lt;attr-spec&gt;</code> is “last”.</td>
</tr>
<tr>
<td>toupper</td>
<td><code>&lt;attr-spec&gt;</code> is an attribute specification. The use of instance specification, including “last”, is allowed. The use of an attribute function is not allowed. The default instance for <code>&lt;attr-spec&gt;</code> is “last”.</td>
</tr>
</tbody>
</table>

Decision files are evaluated from beginning to end. The Decision file is evaluated against the request removing, modifying and/or adding A-V pairs as directed until an `exit` command is encountered. Any remaining lines are not evaluated. The `exit` command specifies the state machine event to give the state machine. The event is used to control the flow through the state machine. For instance, the NAK event will cause the state machine to send a NAK to the request. If the end of the file is reached without executing an `exit` command then the ACK event will be returned to the state machine. See “Finite State Machine (FSM)” on page 256 for more information on FSMs.

Use a pound sign (#) to comment out any lines you do not want applied.

Decision files must be stored in the same directory that contains the RAD-Series Server's other configuration files. There are no required naming conventions for a decision file, but the file name must match its reference in `radius.fsm`, `authfile`, `realm files`, or the default users file.
Attribute Specifications

Attribute specifications have several pieces:

• Vendor Name
• Attribute Name
• Tag Value
• Value
• Instance
• Functions

Vendor Names

When more than one vendor has defined an attribute with the same name, it is necessary to distinguish between them. This is accomplished by prefixing the attribute name with the vendor name, offset by a ':' (colon) character.

For example:

RADIUS:Reply-Message
Cisco:Cisco-AvPair
MERIT:Xvalue

No white space is allowed around the ':' character.

For example:

RADIUS : Reply-Message
RADIUS: Reply-Message
RADIUS :Reply-Message

Are NOT valid. Using these forms will result in a syntax-error load-time error. See “Error Handling” on page 184 for more details.

Vendor names are defined in the RAD-Series Server's vendors file.
Vendor names are case-insensitive (MERIT is the same as Merit).

Attribute Names

Attribute names are specified by simply writing the name of the attribute.

For example:

Reply-Message
Cisco-AvPair
Xvalue

Attribute names are defined in the RAD-Series Server's dictionary file.
Attribute names are case-insensitive (Reply-Message is the same as REPLY-MESSAGE).
**Tag Value**

If the attribute is a tagged attribute then the reference to the attribute may optionally include a tag value using `:<tag>:` format. See “Value Specifications” on page 154 for more information.

**Value**

See “Value Specifications” on page 154 for a description of the value syntax.

**Attribute Instance Specifications**

There can be more than one instance of a given attribute on the request. It is sometimes necessary to specify which instance is of interest. It is sometimes necessary to specify the absolute location of an attribute instance (when inserting, for example).

Attribute instance specifications are provided using `[ ]` syntax following the attribute name. The instance of interest is indicated inside the `[ ]`'s. The instance can be specified numerically using a positive integer constant, using a keyword or using the special symbol `*`.

For example:

```
Reply-Message
Reply-Message[2]
Reply-Message[last]
Reply-Message[*]
```

White space is allowed around and between the `[ ]`'s.

For example:

```
Reply-Message [ 3 ]
Reply-Message[ last]
```

**No instance specification**

When the specific instance is of no consequence, it may be left unspecified. This is equivalent to specifying “last” (see “last keyword” on page 152). See the individual action-command, attribute function and comparison operator descriptions for details.

**Numeric instance specification**

When a specific instance is desired, it may be specified numerically. Instances are numbered from 0 (the first instance). Negative instance numbers are not allowed.

Suppose that:
Keyword instance specification

When a specific instance is desired, it may be specified using one of the following keywords which are case sensitive or the special symbol '*':

- **begin** keyword
  When the beginning of the list is desired (when inserting), use the "begin" keyword. This keyword is only supported by the insert command, on the left side of the '='.
  For example:
  
  ```
  insert Reply-Message[begin] = "This is first"
  ```
  See “insert” on page 147 for details and examples.
  Using this keyword in other places results in an invalid-instance-specification load-time error. See “Error Handling” on page 184 for more details.

- **last** keyword
  When the last instance (the one located closest to the end of the list) of a particular attribute is desired, use the “last” keyword.
  For example:
  
  ```
  Reply-Message[last]
  ```
  This is the default in all situations. See the individual action command, attribute function and comparison operator descriptions for details.
  Suppose that:
  
  ```
  Reply-Message = "abc"
  Reply-Message = "def"
  ```
  Then:
  
  ```
  Reply-Message[last] = "def"
  ```

- ***** keyword
  When all instances are desired, use the '*' symbol.
  For example:
  
  ```
  Reply-Message[*]
  ```
  This form is only supported by the delete and log commands and the count() attribute function. Using this form in unsupported contexts results in an invalid-instance-specification
load-time error. See “Error Handling” on page 184 for more details.

Attribute Functions

Attribute functions are provided using \textit{keyword( \textless attr-spec\textgreater )} syntax.

For example:

\begin{itemize}
  \item \texttt{count( Reply-Message )}
  \item \texttt{count( Reply-Message[0] )}
  \item \texttt{count( Reply-Message[*] )}
\end{itemize}

White space is allowed around and between the ')' characters.

For example:

\begin{itemize}
  \item \texttt{count( Reply-Message )}
  \item \texttt{count( Reply-Message) }
  \item \texttt{count (Reply-Message) }
  \item \texttt{count (Reply-Message )}
\end{itemize}

Are all valid.

There are many possible attribute functions. See description in “Attribute Functions” on page 180 for details.
Value Specifications

Constant values may be specified in various ways depending on the value type. See “Type Compatibility” on page 169 for more details.

1. Integer values

Integer values may be specified as decimal integers, including a leading '-' sign. Integer values cannot have any leading zeros. A tag may also be specified by using :tag: syntax prefixed to the value. The tag value must be in the range of 0 to 31.

For example these are legal:

10
0
-37
:3:10
:0:37

These are NOT legal:

0123
:32:92
:0:-37

Integer values may also be specified as hexadecimal integers. Hexadecimal values are always unsigned.

For example:

0x3
0xB
0x00AB34
:1:0x3
:9:0xf3AB

Integer values can be used with integer, short, octet and tag-int type attributes.

Integer values used with an integer attribute can have a value range of 0 to 4294967295.
Integer values used with a short attribute can have a value range of 0 to 65535.
Integer values used with an octet attribute can have a value range of 0 to 255.
Integer values used with a tagged integer attribute can have a value range of 0 to 16777215.

Violating the value range results in an invalid integer value load-time error. See “Error Handling” on page 184 for more details.

An integer value can be entered as a negative number but the attributes and values will be treated as unsigned numbers when comparisons are performed.

2. Named integer values

Named integer values are enclosed in double quotes "". A tag may be provided by using :tag:
syntax prefixed to the named value.

For example:

```
Service-Type = "FRAMED"
Tunnel-Type = :12:"PPTP"
```

Named integer values are defined in the RAD-Series Server's dictionary file. Named integer values are case-insensitive (FRAMED is the same as Framed). Named integer values can only be used with integer and tag-int type attributes that have defined named values. Named integer values can only be used with the attribute for which they are defined. Using an undefined named value results in an unknown named value load-time error. See “Error Handling” on page 184 for more details.

3. String values

String values are enclosed in double quotes "". There are escape sequences to allow for the inclusion of non-printable characters in a string value. Tags may be specified by using :tag: syntax prefixed to the value.

The defined escape sequences and meanings are:

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>Double Quote</td>
</tr>
<tr>
<td>\</td>
<td>Backslash</td>
</tr>
<tr>
<td>\b</td>
<td>Bell</td>
</tr>
<tr>
<td>\n</td>
<td>Line Feed</td>
</tr>
<tr>
<td>\r</td>
<td>Carriage Return</td>
</tr>
<tr>
<td>\t</td>
<td>Tab</td>
</tr>
<tr>
<td>\h</td>
<td>Backspace</td>
</tr>
<tr>
<td>\f</td>
<td>Form Feed</td>
</tr>
<tr>
<td>\xHH</td>
<td>The octet whose value is the specified 2 digit hex number</td>
</tr>
</tbody>
</table>

For example:

```
"a string value"
"and\x20some\x20\"escapes\"\x20\n"
:21:"a string value"
```

String values can be used with string, tag-str and octets type attributes.

The length of a string attribute and/or string value is not limited except by memory. However, if a string attribute ultimately is inserted into a RADIUS packet then the RAD-Series Server will enforce the following maximums and if violated will result in logging the error in the logfile and dropping the request:

- string and octets: 253 characters
- tag-str: 252 characters
- vendor specific string and octets: 247 characters
- vendor specific tag-str: 246 characters
4. IP Address values

IP Address values are enclosed in double quotes "". IPv4 address values must be specified in standard dotted-quad notation. IPv6 address values must be specified in IPv6 standard notation.

For example:

"1.2.3.4"
"2001:1:2::3"

The use of an invalid IP address results in a syntax-error load-time error. See “Error Handling” on page 184 for more details.

5. IPv6prefix values

The IPv6 prefixed values are enclosed in double quotes "". The IPv6 prefixed values must be specified in IPv6 subnet standard notation.

For example:

"1:2:3:4::/64"

The use of an invalid IPv6 prefixed address results in a syntax-error load-time error. See “Error Handling” on page 184 for more details.

6. InterfaceId values

The InterfaceId values are enclosed in double quotes "". The InterfaceId values must be specified in “hhhh:hhhh:hhhh:hhhh” standard notation.

7. Date values

There is no provision for specifying date value constants at this time. The value of date type attributes may be compared and copied. It is only date value constants that are not supported.

The use of a constant value in conjunction with a date type attribute results in a syntax-error load-time error. See “Error Handling” on page 184 for more details.

8. Tag-Str values

Attributes of type Tag-Str use string values. See String values (item 3 above) for details.

9. Tag-Int values

Attributes of type Tag-Int use integer and named integer values. See Integer values (item 1 above) and Named integer values (item 2 above) for details.

10. Octets values
Attributes of type octets use string values. See String values (item 3 above) for details.

11. Octet values

Attributes of type octet use integer values. See Integer values (item 1 above) for details.

12. Short values

Attributes of type short use integer values. See Integer values (item 1 above) for details.

**Attribute Value Handling**

**Attributes in RADIUS Messages**

Each attribute in a RADIUS message has several fields: attribute code, attribute length, tag and value. For tagged-string attributes, the tag field is optionally present. For vendor-specific attributes, the value field has several sub-fields: vendor code, attribute code, attribute length (details vary by vendor and/or attribute code). See the RADIUS RFCs for additional details.

**Attributes in the RAD-Series Server**

In the RAD-Series Server, attributes have several fields: vendor code, attribute code, tag and value. For all attributes, the tag field and the vendor code field are always present.

**Tagged Attributes and the Advanced Policy Language**

In the RAD-Series Server advanced policy language, the tag field of tagged attributes and the value field of tagged attributes are treated separately.

For conditional expressions in the If command, comparisons consider only the value field of attributes and constants. The tag field is ignored.

For the **insert** command, the tag field from the value on the right hand side of the '=' is preserved in the inserted attribute.

For the **modify** command, the tag field from the value on the right hand side of the '=' is ignored. The tag field of the modified (target) attribute is left unchanged.

For attribute functions that operate on string values (length, substr, tolower, toupper), only the value field is considered. The tag field is ignored. For attribute functions that return the same type of attribute as their parameter (substr, tolower, toupper), the tag field of the source attribute is preserved in the function return value.
Operators

The following operators may be used:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equal to, see “= Operator” on page 159</td>
</tr>
<tr>
<td>!=</td>
<td>Not equal to, see “!= Operator” on page 160</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than, see “&gt; Operator” on page 163</td>
</tr>
<tr>
<td>&lt;</td>
<td>Less than, see “&lt; Operator” on page 161</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal to, see “&gt;= Operator” on page 164</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal to, see “&lt;= Operator” on page 162</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td>Logical AND, see “&amp;&amp; Operator” on page 166</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>!</td>
<td>Logical NOT, see “! Operator” on page 167</td>
</tr>
<tr>
<td>()</td>
<td>Parentheses, see “() Operator” on page 167</td>
</tr>
</tbody>
</table>

Comparison operators

General comparison operator

1. Syntax
   
   `<value1> <operator> <value2>`

2. Parameters
   
   `<value1>` and `<value2>` are value expressions.

   `<value1>` and `<value2>` may use attribute-specifications. The use of instance specification, including “last”, is allowed. The use of attribute functions is allowed.

   Either `<value1>` or `<value2>` (or both) must refer to an attribute.

   This determines the type for the comparison.

   The types of `<value1>` and `<value2>` must be compatible. See “Type Compatibility” on page 169 for details.

   If `<value1>` or `<value2>` refers to an attribute, the default instance is “last”.

3. Operation
   
   Returns a boolean value that indicates the result of the comparison.

   If `<value1>` or `<value2>` refers to an attribute that is a tagged type (tag-int or tag-str), only the value portion is used for comparison purposes. See “Tagged Attributes and the
Advanced Policy Language” on page 157.

For string and octets type values the comparison is performed using the native collation sequence of the system (ASCII), in a case-sensitive fashion. Extended characters (those outside the 7-bit ASCII range) are considered as positive values; in other words, characters are considered to be unsigned.

For integer type values the comparison is performed in a signed fashion, using native system byte ordering.

For IP Address type values the comparison is performed in an unsigned fashion, using big-endian (network/MSB-first) byte ordering.

For date type values the comparison is performed in an unsigned fashion, using native system byte ordering.

4. Examples

Some equivalent specifications (NAS-Port is an example):

- NAS-Port
- NAS-Port[last]

Instance specifications that are allowed:

- NAS-Port
- NAS-Port[0]
- NAS-Port[302]
- NAS-Port[last]

Instance specifications that are NOT allowed:

- NAS-Port[begin]
- NAS-Port[*]

Using any of these specifications results in an invalid-instance-specification load-time error. See “Error Handling” on page 184 for more details.

See the individual comparison operator descriptions below for more complete examples.

= Operator

1. Syntax

   \(<value1> = <value2>\)

2. Parameters

   See Parameters in “General comparison operator” on page 158 for details.

3. Operation

   Compares two values for equality:

   false: \(<value1>\) not equal to \(<value2>\)
   true: \(<value1>\) equal to \(<value2>\)

   See Operation in “General comparison operator” on page 158 for more details.

   If \(<value1>\) or \(<value2>\) refers to an attribute for which there are no instances on the request, the comparison yields false.
4. Examples

Suppose that:

\[ \text{NAS-Port} = 2 \]

Then:

\[ \text{NAS-Port} = 2 \text{ is true} \]
\[ \text{NAS-Port} = 3 \text{ is false} \]
\[ 2 = \text{NAS-Port} \text{ is true (same as } 2 = \text{NAS-Port}[\text{last}] \) \]
\[ 3 = \text{NAS-Port} \text{ is false (same as } 3 = \text{NAS-Port}[\text{last}] \) \]

Suppose that:

\[ \begin{align*}
\text{NAS-Port} &= 2 \\
\text{NAS-Port} &= 3
\end{align*} \]

Then:

\[ \begin{align*}
\text{NAS-Port} &= 2 \text{ is false} \\
\text{NAS-Port} &= 3 \text{ is true} \\
\text{NAS-Port}[0] &= 2 \text{ is true} \\
\text{NAS-Port}[1] &= 2 \text{ is false} \\
\text{NAS-Port}[0] &= 3 \text{ is false} \\
\text{NAS-Port}[1] &= 3 \text{ is true} \\
\text{NAS-Port} &= \text{NAS-Port} \text{ is true} \\
\text{NAS-Port}[\text{last}] &= \text{NAS-Port} \text{ is true} \\
2 &= \text{NAS-Port} \text{ is false (same as } 2 = \text{NAS-Port}[\text{last}] \) \]
\[ 3 = \text{NAS-Port} \text{ is true (same as } 3 = \text{NAS-Port}[\text{last}] \) \]
\[ \text{NAS-Port}[2] = 2 \text{ is false (NAS-Port}[2] \text{ is not present)} \] 

Suppose that:

\[ \begin{align*}
\text{Reply-Message} &= "abc" \\
\text{Tunnel-Password} &= :2:"abc" \\
\text{Tunnel-Password} &= :1:"abc"
\end{align*} \]

Then:

\[ \begin{align*}
\text{Tunnel-Password}[0] &= \text{Tunnel-Password}[1] \text{ is true} \\
\text{Tunnel-Password}[0] &= \text{Reply-Message} \text{ is true} \\
\text{Tunnel-Password}[0] &= "abc" \text{ is true} \\
\text{Reply-Message} &= \text{Tunnel-Password} \text{ is true} \\
"abc" &= \text{Tunnel-Password}[0] \text{ is true} \\
:21:"abc" &= \text{Tunnel-Password} \text{ is true} \\
:21:"abc" &= \text{Reply-Message} \text{ is true}
\end{align*} \]

!= Operator

1. Syntax

\[ <value1> \neq <value2> \]

2. Parameters

See Parameters in “General comparison operator” on page 158 for details.

3. Operation
Compares two values for inequality:

- false: `<value1>` equal to `<value2>`
- true: `<value1>` not equal to `<value2>`

See Operation in “General comparison operator” on page 158 for more details.

If `<value1>` or `<value2>` refers to an attribute for which there are no instances on the request, the comparison yields true.

### 4. Examples

Suppose that:

- `NAS-Port = 2`

Then:

- `NAS-Port != 2` is false
- `NAS-Port != 3` is true
- `2 != NAS-Port` is false
- `3 != NAS-Port` is true
- `NAS-Port[2] != 2` is true (`NAS-Port[2]` is not present)

Suppose that:

- `NAS-Port = 2`
- `NAS-Port = 3`

Then:

- `NAS-Port != 2` is true
- `NAS-Port[0] != 2` is false
- `NAS-Port[1] != 2` is true
- `NAS-Port != 3` is false
- `NAS-Port != 4` is true
- `2 != NAS-Port` is true (same as `2 != NAS-Port[last]`)
- `3 != NAS-Port` is false (same as `3 != NAS-Port[last]`)
- `4 != NAS-Port` is true (same as `4 != NAS-Port[last]`)
- `NAS-Port[2] != 7` is true (`NAS-Port[2]` is not present)

Suppose that:

- `Tunnel-Password = :2:"abc"`
- `Tunnel-Password = :1:"abc"`

Then:

- `Tunnel-Password[0] != Tunnel-Password[1]` is false

### < Operator

1. Syntax

   `<attr1> < <attr2>`

2. Parameters

   See Parameters in “General comparison operator” on page 158 for details.

3. Operation
Compares two values for less than:

false: `<value1>` not less than
true: `<value1>` less than `<value2>`

See Operation in “General comparison operator” on page 158 for more details.

If `<value1>` or `<value2>` refers to an attribute for which there are no instances on the request, the comparison yields false.

4. Examples

Suppose that:

NAS-Port = 2

Then:

`NAS-Port < 2` is false
`NAS-Port < 3` is true
`2 < NAS-Port` is false
`37 < NAS-Port[2]` is false (NAS-Port[2] is not present)

Suppose that:

NAS-Port = 2
NAS-Port = 3

Then:

`NAS-Port < 2` is false
`NAS-Port < 3` is false
`NAS-Port < 4` is true
`2 < NAS-Port` is true (same as `2 < NAS-Port[last]`)

Suppose that:

Tunnel-Type = :2:"PPTP" (this has the value 1)
Tunnel-Type = :1:"VLAN" (this has the value 13)

Then:

`Tunnel-Type[0] < Tunnel-Type[1]` is true (same as `1 < 13`)
`Tunnel-Type < 7` is false (same as `13 < 7`)

Suppose that:

Tunnel-Password = :2:"abc"
Tunnel-Password = :1:"def"

Then:

`Tunnel-Password[0] < Tunnel-Password[1]` is true

**<=$ Operator**

1. Syntax

   `<attr1> <= <attr2>`

2. Parameters

   See Parameters in “General comparison operator” on page 158 for details.
3. Operation

Compares two values for less than or equal to:

false: `<value1>` not less than or equal to `<value2>`
true: `<value1>` less than or equal to `<value2>`

See Operation in “General comparison operator” on page 158 for more details.

If `<value1>` or `<value2>` refers to an attribute for which there are no instances on the request, the comparison yields false.

4. Examples

Suppose that:

NAS-Port = 2

Then:

NAS-Port <= 2 is true
NAS-Port <= 3 is true
2 <= NAS-Port is true
3 <= NAS-Port is false
NAS-Port[2] <= 55 is false (NAS-Port[2] is not present)

Suppose that:

NAS-Port = 2
NAS-Port = 3

Then:

NAS-Port <= 2 is false
NAS-Port <= 3 is true
2 <= NAS-Port is true (same as 2 <= NAS-Port[last])
3 <= NAS-Port is true (same as 3 <= NAS-Port[last])

Suppose that:

Tunnel-Password = :2:"abc"
Tunnel-Password = :1:"abc"
Tunnel-Password = :3:"def"

Then:

Tunnel-Password[0] <= Tunnel-Password[1] is true
Tunnel-Password[0] <= Tunnel-Password[2] is true

> Operator

1. Syntax

   `<attr1> > <attr2>`

2. Parameters

   See Parameters in “General comparison operator” on page 158 for details.

3. Operation

   Compares two values for greater than:
false: `<value1>` not greater than `<value2>`
true: `<value1>` greater than `<value2>`

See Operation in “General comparison operator” on page 158 for more details.

If `<value1>` or `<value2>` refers to an attribute for which there are no instances on the request, the comparison yields false.

4. Examples

Suppose that:

NAS-Port = 2

Then:

NAS-Port > 1 is true
NAS-Port > 2 is false
NAS-Port > 3 is false
NAS-Port > 4 is false
1 > NAS-Port is false
2 > NAS-Port is false
3 > NAS-Port is true
4 > NAS-Port is true
NAS-Port[2] > 1 is false (NAS-Port[2] is not present)

Suppose that:

NAS-Port = 2
NAS-Port = 3

Then:

NAS-Port > 1 is true
NAS-Port > 2 is true
NAS-Port > 3 is false
NAS-Port > 4 is false
1 > NAS-Port is false
2 > NAS-Port is false
3 > NAS-Port is false
4 > NAS-Port is true

Suppose that:

Tunnel-Password = :2:"def"
Tunnel-Password = :1:"abc"

Then:

Tunnel-Password[0] > Tunnel-Password[1] is true

**>= Operator**

1. Syntax

   `<attr1> >= <attr2>`

2. Parameters

   See Parameters in “General comparison operator” on page 158 for details.
3. Operation

Compares two values for greater than or equal to:

false: `<value1>` not greater than or equal to `<value2>`
true: `<value1>` greater than or equal to `<value2>`

See Operation in “General comparison operator” on page 158 for more details.

If `<value1>` or `<value2>` refers to an attribute for which there are no instances on the request, the comparison yields false.

4. Examples

Suppose that:

```
  NAS-Port = 2
```

Then:

```
NAS-Port >= 1 is true
NAS-Port >= 2 is true
NAS-Port >= 3 is false
NAS-Port >= 4 is false
1 >= NAS-Port is false
2 >= NAS-Port is true
3 >= NAS-Port is true
4 >= NAS-Port is true
NAS-Port[2] >= 2 is false (NAS-Port[2] is not present)
```

Suppose that:

```
  NAS-Port = 2
  NAS-Port = 3
```

Then:

```
NAS-Port >= 1 is true
NAS-Port >= 2 is true
NAS-Port >= 3 is true
NAS-Port >= 4 is false
1 >= NAS-Port is false
2 >= NAS-Port is false
3 >= NAS-Port is true
4 >= NAS-Port is true
```

Suppose that:

```
  Tunnel-Password = :2:"abc"
  Tunnel-Password = :1:"abc"
  Tunnel-Password = :3:"def"
```

Then:

```
Tunnel-Password[0] >= Tunnel-Password[1] is true
```
Boolean Expressions

&& Operator

1. Syntax
   
   `<left-expr> && <right-expr>`

2. Parameters
   
   `<left-expr>` and `<right-expr>` are boolean expressions.

3. Operation
   
   The `&&` operator evaluates the `<left-expr>` always. The `<right-expr>` is evaluated only when the `<left-expr>` evaluates to a true value.
   
   This is the traditional short-circuit evaluation most people expect.
   
   The value is true if both the `<left-expr>` and `<right-expr>` evaluate to true values.
   
   Otherwise the value is false.

4. Examples
   
   Suppose that:
   
   NAS-Port = 2
   Reply-Message = "hello"

   Then:
   
   NAS-Port = 2 && Reply-Message = "hello" is true

|| Operator

1. Syntax
   
   `<left-expr> || <right-expr>`

2. Parameters
   
   `<left-expr>` and `<right-expr>` are boolean expressions.

3. Operation
   
   The `||` operator evaluates the `<left-expr>` always. The `<right-expr>` is evaluated only when the `<left-expr>` evaluates to a false value.
   
   This is the traditional short-circuit evaluation most people expect.
   
   The value is true if either the `<left-expr>` or the `<right-expr>` evaluates to a true value.
   
   Otherwise the value is false.

4. Examples
   
   Suppose that:
NAS-Port = 2
Reply-Message = "hello"

Then:
NAS-Port = 2 || Reply-Message = "xyz" is true
NAS-Port = 7 || Reply-Message = "hello" is true

! Operator
1. Syntax
   ! <expr>

2. Parameters
   <expr> is a Boolean expression.

3. Operation
   The ! operator evaluates the <expr>. The value is the boolean complement of the <expr> value.

4. Examples
   Suppose that:
   
   NAS-Port = 2
   
   Then:
   ! NAS-Port = 3 is true
   ! NAS-Port > 1 is true
   ! NAS-Port = 2 is false

() Operator
1. Syntax
   ( <expr> )

2. Parameters
   <expr> is a boolean expression.

3. Operation
   The <expr> is evaluated. The value is the result of the evaluation.

4. Examples
   Suppose that:
   
   NAS-Port = 2
   
   Then:
(NAS-Port = 2) is true
((NAS-Port = 2)) is true
(NAS-Port = 3) is false
((NAS-Port = 3)) is false

**Operator precedence and association**

When multiple operators appear in a boolean expression, the following precedence and association rules are applied.

1. **Precedence rules**

   The precedence rules in decreasing order are:
   
   ()
   !
   && ||

2. **Association rules**

   The association rules are:
   
   && left-to-right
   || left-to-right
   ! right

3. **Examples:**

   The boolean expression:
   
   Reply-Message = "hello" && NAS-Port > 7 ||
   Reply-Message = "goodbye" || Reply-Message = "nothing"

   Is fully parenthesized as:
   
   ( ( (Reply-Message = "hello") && (NAS-Port > 7) ) ||
   (Reply-Message = "goodbye") ) ||
   (Reply-Message = "nothing")

   And is evaluated:
   
   if ( Reply-Message = "hello" )
   if ( NAS-Port > 7 )
   return true
   if ( Reply-Message = "goodbye" )
   return true
   if ( Reply-Message = "nothing" )
   return true
   return false

   The boolean expression:
   
   Reply-Message = "goodbye" ||
   ! Reply-Message = "hello" && NAS-Port > 7

   Is fully parenthesized as:
( (Reply-Message = "goodbye") ||
( ! (Reply-Message = "hello") )
&&
(NAS-Port > 7)

And is evaluated:
if ( Reply-Message = "goodbye" )
   if ( NAS-Port > 7 )
      return true
   else
      return false
else
   if ( Reply-Message = "hello" )
      return false
   else
      if ( NAS-Port > 7 )
         return true
      else
         return false

**Type Compatibility**

Attribute types are compatible if the value-types are the same.

Integer-value attribute types:
   integer
   tag-int
   short
   octet

String-value attribute types:
   string
   tag-str
   octets

Date-value attribute types:
   date

IPv4-address-value attribute types:
   ipaddr

IPv6-address-value attribute types:
   ipv6addr

IPv6-prefix-value attribute types:
   ipv6prefix

InterfaceId-value attribute types:
   interfaceid

It is not permissible to mix attributes from different value-type groups. Doing so results in a type-
mismatch load-time error. See “Error Handling” on page 184 for more details.

Since an integer attribute can be copied into any of the other three integer type attributes, it is possible to end up with a value that does not fit into that attribute when placed into a RADIUS packet. When the RAD-Series Server encounters excess bits while putting an attribute into the packet it will log the issue in the logfile and ignore the excess high order bits.

**Action Commands**

**if Command**

1. **Syntax**

   if ( <bool.expr> ) { <action-list1> } else { <action-list2> }

2. **Parameters**

   - `<bool.expr>` is a boolean expression. See “Boolean Expressions” on page 166.
   - `<action-list1>` and `<action-list2>` are sequences of action commands that may include additional if commands, nested to an arbitrary depth.

   When the else clause is omitted, `<action-list2>` may be considered an empty sequence of action commands.

3. **Operation**

   Conditionally evaluates policy actions.

   Evaluates the `<bool.expr>`. See “Tagged Attributes and the Advanced Policy Language” on page 157 for how tags are handled.

   If the result of evaluating `<bool.expr>` is true, evaluates `<action-list1>`.

   If the result of evaluating `<bool.expr>` is false (and an else clause is present), evaluates `<action-list2>`.

4. **Examples**

   - Suppose that:
     
     Session-Limit[0] = 10
     Session-Limit[1] = 300

     **The commands:**
     
     if ( Session-Limit[1] < 30 )
     {
         modify Session-Limit[1] = 30
     }
     else
     {
         if ( Session-Limit[1] > 240 )
         {

Interlink Networks, LLC.  Page 170
modify Session-Limit[1] = 240
}
}

Results in:
  Session-Limit[0] = 10
  Session-Limit[1] = 240

• Suppose that:
  NAS-IP-Address = “192.168.1.2"
  NAS-Identifier = “fred”
  Port-Limit = 23

The commands:
  if ( (NAS-IP-Address = "192.168.1.2") &&
      ((NAS-Identifier = “jack”) || (Port-Limit > 20))
  )
  {
    exit “NAK”
  }

Results in:
  Request being rejected.

**delete Command**

1. Syntax
   
   delete <attr-spec>

2. Parameters
   
   <attr-spec> is an attribute specification, see “Attribute Specifications” on page 150. The use of instance specification, including ’*’ is allowed. The use of attribute functions is not permitted.

   The default instance for <attr-spec> is “last”.

3. Operation
   
   Deletes the named instance from the request. All instances may be deleted by using the ’*’ instance specifier.

   If <attr-spec> refers to an instance that is not present, no instances will be deleted. A no-such-instance run-time error is NOT generated in this case.

4. Examples
   
   • Suppose that:
     
     NAS-Port = 2
     Reply-Message = "Hello, world!"
Reply-Message = "So long"
NAS-IP-Address = "2.3.4.5"

The command:
  delete Reply-Message[*]

Results in:
  NAS-Port = 2
  NAS-IP-Address = "2.3.4.5"

• Suppose that:
  NAS-Port = 2
  Reply-Message = "Hello, world!"
  Reply-Message = "So long"
  NAS-IP-Address = "2.3.4.5"

The command:
  delete Reply-Message

Results in:
  NAS-Port = 2
  Reply-Message = "Hello, world!"
  NAS-IP-Address = "2.3.4.5"

• Suppose that:
  NAS-Port = 2
  Reply-Message = "Hello, world!"
  Reply-Message = "So long"
  NAS-IP-Address = "2.3.4.5"

The command:
  delete Reply-Message[0]

Results in:
  NAS-Port = 2
  Reply-Message = "So long"
  NAS-IP-Address = "2.3.4.5"

• Suppose that:
  NAS-Port = 2
  Reply-Message = "Hello, world!"

The command:
  delete NAS-IP-Address[*]

Results in:
  NAS-Port = 2
  Reply-Message = " Hello, world!"

• Suppose that:
  NAS-Port = 2
  Reply-Message = "Hello, world!"
The command:
    delete NAS-IP-Address[0]

Results in:
    NAS-Port = 2
    Reply-Message = "Hello, world!"

• Suppose that:
    NAS-Port = 2
    Reply-Message = "Hello, world!"

The command:
    delete NAS-IP-Address[last]

Results in:
    NAS-Port = 2
    Reply-Message = "Hello, world!"

insert Command

1. Syntax

    insert <attr-spec> = <value-expr>

2. Parameters

    <attr-spec> is an attribute specification, see “Attribute Specifications” on page 150. The use of instance specification, including “begin” and “last”, is allowed. The use of attribute functions is not allowed.
    The default instance for <attr-spec> is “last”.

    <value-expr> is a value expression.
    <value-expr> may use attribute specification. The use of instance specification, including “last”, is allowed. The use of attribute functions is allowed.
    If <value-expr> refers to an attribute, the default instance is “last”.
    If <value-expr> refers to an instance that is not present, a no-such-instance run-time error occurs. See “Error Handling” on page 184 for details.

    The types of <attr-spec> and <value-spec> must be compatible. See “Type Compatibility” on page 169 for details.

3. Operation

    Insert <attr-spec> into the request, having the value of <value-expr>. See “Tagged Attributes and the Advanced Policy Language” on page 157 for how tags are handled.
    If <attr-spec> refers to an instance that is not present, the location will be the end the list.
    If <attr-spec> refers to a tagged attribute (tag-int or tag-str) and <value-spec> is not a tagged value, the tag for the inserted attribute will be set to 0.
    If <attr-spec> refers to an attribute that is not tagged and <value-spec> is a tagged value, the tag is ignored.
The instance location specified by `<attr-spec>` indicates the desired target location for the inserted instance. The algorithm used is "final opportunity", as opposed to "earliest opportunity". This means inserting "last" is the same as inserting at the end and inserting instance n occurs just before the already-present instance n (or the end if instance n is not already present).

4. Examples

- Suppose that:
  
  NAS-Port = 2  
  Reply-Message = "message#1"  
  Reply-Message = "message#2"  
  NAS-IP-Address = "2.3.4.5"

  The command:
  
  `insert Reply-Message = Reply-Message`

  Results in:
  
  NAS-Port = 2  
  Reply-Message = "message#1"  
  Reply-Message = "message#2"  
  NAS-IP-Address = "2.3.4.5"

- Suppose that:
  
  NAS-Port = 2  
  Reply-Message = "message#1"  
  Reply-Message = "message#2"  
  NAS-IP-Address = "2.3.4.5"

  The command:
  
  `insert Reply-Message[0] = "a new message"`

  Results in:
  
  NAS-Port = 2  
  Reply-Message = "a new message"  
  Reply-Message = "message#1"  
  Reply-Message = "message#2"  
  NAS-IP-Address = "2.3.4.5"

- Suppose that:
  
  NAS-Port = 2  
  Reply-Message = "message#1"  
  Reply-Message = "message#2"  
  NAS-IP-Address = "2.3.4.5"

  The command:
  
  `insert Reply-Message[1] = "a new message"`

  Results in:
  
  NAS-Port = 2  
  Reply-Message = "message#1"
• Suppose that:
  
  NAS-Port = 2
  Reply-Message = "message#1"
  Reply-Message = "message#2"
  NAS-IP-Address = "2.3.4.5"

  The command:
  

  Results in:
  
  NAS-Port = 2
  Reply-Message = "message#1"
  Reply-Message = "message#2"
  Reply-Message = "a new message"
  NAS-IP-Address = "2.3.4.5"

• Suppose that:
  
  NAS-Port = 2
  Reply-Message = "message#1"
  Reply-Message = "message#2"
  NAS-IP-Address = "2.3.4.5"

  The command:
  
  insert Reply-Message[last] = "a new message"

  Results in:
  
  NAS-Port = 2
  Reply-Message = "message#1"
  Reply-Message = "message#2"
  NAS-IP-Address = "2.3.4.5"
  Reply-Message = "a new message"

• Suppose that:
  
  NAS-Port = 2
  NAS-IP-Address = "2.3.4.5"

  The command:
  
  insert Reply-Message[begin] = "Hello, world!"

  Results in:
  
  Reply-Message = "Hello, world!"
  NAS-Port = 2
  NAS-IP-Address = "2.3.4.5"

• Suppose that:
  
  Reply-Message = "hello"

  The command:
insert Tunnel-Password = Reply-Message

Results in:
    Reply-Message = "hello"
    Tunnel-Password = :0:"hello"

- Suppose that:
    Tunnel-Password = :2:"abc"

The command:
    insert Reply-Message = Tunnel-Password

Results in:
    Tunnel-Password = :2:"abc"
    Reply-Message = "abc"

- Suppose that:
    Tunnel-Password = :2:"abc"

The command:
    insert Tunnel-Password = :3:"def"

Results in:
    Tunnel-Password = :2:"abc"
    Tunnel-Password = :3:"def"

- Suppose that:
    Reply-Message = "hello"

The command:
    insert Reply-Message = :3:"def"

Results in:
    Reply-Message = "hello"
    Reply-Message = "def"

- Suppose that:
    Reply-Message = "abc"

The command:
    insert NAS-Port = count( Reply-Message[*] )

Results in:
    Reply-Message = "abc"
    NAS-Port = 1

**modify Command**

1. Syntax

    modify <attr-spec> = <value-spec>
2. Parameters

<attr-spec> is an attribute specification, see “Attribute Specifications” on page 150. The use of instance specification, including “last”, is allowed. The use of attribute functions is not allowed.

The default instance for <attr-spec> is “last”.

If <attr-spec> refers to an instance that is not present, a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.

<value-spec> is a value specification.
<value-spec> may use attribute specifications. The use of instance specification, including “last”, is allowed. The use of attribute functions is allowed.

If <value-spec> refers to an attribute, the default instance for <value-spec> is “last”.

If <value-spec> refers to an instance that is not present, a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.

The value types for <attr-spec> and <value-spec> must be compatible. See “Type Compatibility” on page 169 for details.

3. Operation

Modifies <attr-spec> to have the value of <value-spec>. See “Tagged Attributes and the Advanced Policy Language” on page 157 for how tags are handled.

If <attr-spec> refers to a tagged attribute (tag-int or tag-str) and <value-spec> is a tagged value, the tag of <attr-spec> is not modified. Only the value of <attr-spec> is modified.

4. Examples

• Suppose that:

  Reply-Message = "123"
  Reply-Message = "456"

  The command:

  modify Reply-Message = "abc"

  Results in:

  Reply-Message = "123"
  Reply-Message = "abc"

• Suppose that:

  Reply-Message = "123"
  Reply-Message = "456"

  The command:

  modify Reply-Message = Reply-Message[0]

  Results in:

  Reply-Message = "123"
  Reply-Message = "123"

• Suppose that:

  NAS-Identifier = "abc.def.ghi"
The command:
   modify NAS-Identifier = "wxyz"
Results in:
   NAS-Identifier = "wxyz"

• Suppose that:
   Tunnel-Password = :2:"abc"
   The command:
   modify Tunnel-Password = "def"
Results in:
   Tunnel-Password = :2:"def"

• Suppose that:
   Tunnel-Password = :2:"abc"
   The command:
   modify Tunnel-Password = :4:"ghi"
Results in:
   Tunnel-Password = :2:"ghi"

• Suppose that:
   Reply-Message = "hello"
   Tunnel-Password = :17:"abc"
   The command:
   modify Reply-Message = Tunnel-Password
Results in:
   Reply-Message = "abc"
   Tunnel-Password = :17:"abc"

• Suppose that:
   Reply-Message = "hello"
   Tunnel-Password = :17:"abc"
   The command:
   modify Tunnel-Password = Reply-Message
Results in:
   Reply-Message = "hello"
   Tunnel-Password = :17:"hello"

• Suppose that:
   NAS-Port = 7
   Reply-Message = "abc"
   Reply-Message = "def"
   The command:
   modify NAS-Port = count( Reply-Message[*] )
Results in:
  
  NAS-Port = 2
  Reply-Message = "abc"
  Reply-Message = "def"

• Suppose that:
  
  Reply-Message = "abc"
  Reply-Message = "def"

The command:
  
  modify Reply-Message[0] = Reply-Message[1]

Results in:
  
  Reply-Message = "def"
  Reply-Message = "def"

exit Command

1. Syntax
   
extit "<event-name>"

2. Parameters
   
   <event-name> must be a quoted string.
   
   <event-name> must specify an event that is defined. There are a number of predefined
   events. Additional events may be defined in the FSM file using “%event <name>” syntax.
   See “Events” on page 258 for more detailed information on finite state machine events.

   Event names are case-insensitive (MyEvent is the same as MYEVENT).

3. Operation
   
   Terminates evaluation of the policy and returns the named event to the finite state machine.
   See “FSM Interaction” on page 185 for more details.

   The use of an undefined event name results in an undefined-event load-time error. See “Error
   Handling” on page 184 for more details.

4. Examples
   
extit "ACK"

log Command

1. Syntax
   
   log "<log-level>" "<log-message>"
   log "<log-level>" "<log-message>", <attr-spec>
   log "<log-level>" "<log-message>", <attr-spec>, ... <attr-spec>
2. Parameters

<log-level> must be a quoted string.
<log-level> must be a log-level type:
   FATAL, ERROR, CRITICAL, ALERT, WARNING, INFO
<log-level> is case-insensitive ("ERROR" same as "Error").

<log-message> must be a quoted string.

Multiple instances for <attr-spec> are allowed and cause all named instances to be reported in the logfile, see “Attribute Specifications” on page 150. The use of instance specification, including “last” and “*”, is allowed. The default instance specification for the attributes in the log command is “last”.

If <attr-spec> refers to an instance that is not present, this will be indicated in the logfile output. A no-such-instance run-time error will NOT be generated in this case.

3. Operation

Causes a message to be written to the logfile.

When attributes are specified, they are reported one value per line in the logfile. Multiple instances are reported one value per line as well.

All log output lines will include the file/line location of the log command that generated the message.

All log output will be generated using the standard logging functions which puts a timestamp on the output line.

4. Example

   log "Warning" "This user should not come in through this NAS",
       User-Name, NAS-IP-Address

Attribute Functions

- count function
  1. Syntax
     count ( <attr-spec> )
  2. Parameters
     <attr-spec> specifies an attribute (possibly including vendor or instance), see “Attribute Specifications” on page 150.
     The default instance for <attr-spec> is 'last'.
  3. Operation
     Returns an integer value that indicates the number of instances.
     If <attr-spec> refers to instance '*', then count () yields the total number of instances of <attr-spec> that are present.
     If <attr-spec> refers to a specific instance that is present, then count () yields the value 1.
If <attr-spec> refers to an instance that is not present, then count() yields the value 0. A no-such-instance run-time error is NOT generated in this case.

- **length function**
  1. Syntax
     
     ```
     length ( <attr-spec> )
     ```
  2. Parameters
     
     `<attr-spec>` specifies an attribute (possibly including vendor or instance) which must be of type String, Tag-Str, or Octets, see “Attribute Specifications” on page 150. The default instance for `<attr-spec>` is 'last'.
  3. Operation
     
     Returns an integer value that indicates the number characters in the string attribute. For a Tag-Str attribute it does not include the tag octet. See “Tagged Attributes and the Advanced Policy Language” on page 157 for how tags are handled.

     If `<attr-spec>` refers to an instance that is not present, then a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.

- **substr function**

  **Using 'offset' keyword**
  1. Syntax
     
     ```
     substr ( <attr-spec> offset <start> )
     substr ( <attr-spec> offset <start> length <number> )
     ```
  2. Parameters
     
     `<attr-spec>` specifies an attribute (possibly including vendor or instance) which must be of type String, Tag-Str, or Octets, see “Attribute Specifications” on page 150. The default instance for `<attr-spec>` is 'last'.

     `<start>` is the offset from the beginning of the string to the first character of the desired substring. It must be a non-negative integer constant.

     `<number>` is the optional length of the desired substring. It must be a non-negative integer constant.

     If “length <number>” is not present then the length defaults to the remainder of the string.
  3. Operation
     
     Returns the requested substring, with same type as the source. See “Tagged Attributes and the Advanced Policy Language” on page 157 for how tags are handled.

     When the length is not specified the remainder of the string value is used.

     If the offset is off the end of the string then substr returns an empty string.

     For example:
     ```
     insert Reply-Message = "a string of characters"
     substr( Reply-Message offset 0 length 8 )
     ```

     Returns the string: "a string".
insert Reply-Message = "a string of characters"
substr( Reply-Message offset 16 length 82 )

Returns the string: “acters”.

insert Reply-Message = "a string of characters"
substr( Reply-Message offset 12 )

Returns the string: "characters".

insert Reply-Message = "a string of characters"
substr( Reply-Message offset 32 )

Returns the empty string: "".

If <attr-spec> refers to an instance that is not present, then a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.

Using 'before' keyword

1. Syntax

   substr ( <attr-spec> before "<before-string>" )
   substr ( <attr-spec> before last "<before-string>" )

2. Parameters

   <attr-spec> specifies an attribute (possibly including vendor or instance) which must be of type String, Tag-Str, or Octets, see “Attribute Specifications” on page 150.
   The default instance for <attr-spec> is 'last'.
   <before-string> must be a quoted string constant.

3. Operation

   Returns the requested substring with same type as the source. See “Tagged Attributes and the Advanced Policy Language” on page 157 for how tags are handled.

   The substring will start from the beginning of the string up to but not including the first occurrence of <before-string> for 'before'.
   The substring will start from the beginning of the string up to but not including the last occurrence of <before-string> for 'before last'.

   When <before-string> is not found the entire string is returned.

For example:

insert Reply-Message = "a string of characters"
substr( Reply-Message before " of" )

Returns the string: "a string".

insert Reply-Message = "a string of characters"
substr( Reply-Message before last "" )

Returns the string: "a string of".

insert Reply-Message = "a string of characters"
substr( Reply-Message before "not-there" )

Returns the entire string: "a string of characters".

If <attr-spec> refers to an instance that is not present, then a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.
error is generated. See “Error Handling” on page 184 for more details.

Using 'after' keyword

1. Syntax
   
   \[
   \text{substr} \ ( \ <\text{attr-spec}> \ \text{after} \ "<\text{after-string}>" \ ) \\
   \text{substr} \ ( \ <\text{attr-spec}> \ \text{after} \ \text{last} \ "<\text{after-string}>" \ )
   \]

2. Parameters
   
   \(<\text{attr-spec}>\) specifies an attribute (possibly including vendor or instance) which must be of type String, Tag-Str, or Octets, see“Attribute Specifications” on page 150.
   
   The default instance for \(<\text{attr-spec}>\) is 'last'.
   
   \(<\text{after-string}>\) must be a quoted string constant.

3. Operation
   
   Returns the requested substring with same type as the source. See “Tagged Attributes and the Advanced Policy Language” on page 157 for how tags are handled.
   
   The substring will start following the first occurrence of \(<\text{after-string}>\) for 'after'.
   
   The substring will start following the last occurrence of \(<\text{after-string}>\) for 'after last'.
   
   When \(<\text{after-string}>\) is not found the empty string is returned.
   
   For example:
   
   \[
   \text{insert Reply-Message} = "a string of characters" \\
   \text{substr( Reply-Message after " of")}
   \]
   
   Returns the string: " characters".
   
   \[
   \text{insert Reply-Message} = "a string of characters" \\
   \text{substr( Reply-Message after last "\")}
   \]
   
   Returns the string: "characters".
   
   \[
   \text{insert Reply-Message} = "a string of characters" \\
   \text{substr( Reply-Message after "not-there")}
   \]
   
   Returns the empty string: "".
   
   If \(<\text{attr-spec}>\) refers to an instance that is not present, then a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.

• tolower function

1. Syntax
   
   \[
   \text{tolower} \ ( \ <\text{attr-spec}> \ )
   \]

2. Parameters
   
   \(<\text{attr-spec}>\) specifies an attribute (possibly including vendor or instance) which must be of type String, Tag-Str, or Octets, see“Attribute Specifications” on page 150.
   
   The default instance for \(<\text{attr-spec}>\) is 'last'.

3. Operation
   
   Returns the string value converted to lowercase with same type as the source. See “Tagged
Attributes and the Advanced Policy Language” on page 157 for how tags are handled.

If <attr-spec> refers to an instance that is not present, then a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.

- **toupper** function
  1. Syntax
     
     toupper ( <attr-spec> )
  2. Parameters
     
     <attr-spec> specifies an attribute (possibly including vendor or instance) which must be of type String, Tag-Str, or Octets, see “Attribute Specifications” on page 150. The default instance for <attr-spec> is 'last'.
  3. Operation
     
     Returns the string value converted to uppercase with same type as the source. See “Tagged Attributes and the Advanced Policy Language” on page 157 for how tags are handled.

     If <attr-spec> refers to an instance that is not present, then a no-such-instance run-time error is generated. See “Error Handling” on page 184 for more details.

**Error Handling**

This section describes how error conditions are handled by the advanced policy engine.

There are two types of errors: load-time errors and run-time errors.

1. Load-time Errors

The following load-time errors are defined:

   syntax error
   type mismatch
   invalid instance specification
   invalid integer value
   invalid IP address constant
   invalid tag value
   unknown named value
   undefined event
   undefined value

When a load-time error occurs, the decision file is considered invalid; it is not loaded. A message in the logfile will indicate the location of the problem by file and line number. An ERROR event is returned to the state machine. See “FSM Interaction” on page 185 for more details.

2. Run-time Errors

The following run-time errors are defined:

   no such instance
When a run-time error occurs, the policy evaluation is terminated. A message in the logfile will indicate the location of the problem by file and line number. An ERROR event is returned to the state machine. See “FSM Interaction” on page 185 for more details.

**FSM Interaction**

This section describes how the advanced policy engine interacts with the finite state machine.

1. **Invoking Policies**
   
   Policies are invoked using the POLICY action in the FSM. The Xstring parameter uses a URL-like syntax to specify the policy to be invoked.
   
   Example:
   
   ```
   decisionfile://MyPolicy.policy
   ```
   
   See “Calling Decision Files” on page 187 for more details on invoking policies.
   
   When a policy is invoked, it is evaluated.
   
   When a policy is evaluated, it may return an event to the state machine to direct the subsequent processing of a request.

2. **Returning Events**

   There are several ways to return an event to the state machine:

   - **exit Command**
   
   Default Event
   
   Error Condition

   - **exit Command**
   
   Using the `exit` command causes the evaluation of the policy to be terminated. The specified event is returned to the state machine.

   - **Default Event**
   
   If evaluation of a decision file reaches the end without encountering an `exit` command, the default event is returned to the state machine.

   - **Error Conditions**
   
   When an error occurs, an ERROR event is returned to the state machine.
**Internal Attributes**

The following Interlink and Merit specific attributes are useful in policy conditions or replies.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interlink-Packet-Code</td>
<td>An integer that indicates what type of RADIUS message has been received: either 1 (Access-Request) or 4 (Accounting-Request).</td>
</tr>
<tr>
<td>Interlink-Proxy-Action</td>
<td>A string (normally determined by information in the Access-Request or Accounting-Request) that indicates the name of the starting event in the FSM when the RAD-Series Server receives a RADIUS message. You can preempt this value by modifying the request-ingress.grp decision file to determine the start event.</td>
</tr>
<tr>
<td>Interlink-Proxy-Target</td>
<td>A string that identifies the proxy target host system. The proxy target host system must be listed in the RAD-Series Server’s clients file.</td>
</tr>
<tr>
<td>Interlink-Reply-Status</td>
<td>An integer that contains an FSM code representing the reply status:</td>
</tr>
</tbody>
</table>
|                           | • ACK -- Access-Accept or Accounting-Response  
|                           | • NAK -- Access-Reject  
|                           | • ACC_CHAL -- Access-Challenge  

This attribute is used to preserve the reply status of a request while applying reply post-processing policy.

This attribute is used to preserve the reply status of a proxy response while applying proxy receive response policy.

| Interlink-Request-Type    | A string that identifies the request type:  
|                           | • "REQUEST" -- a normal request  
|                           | • "CONTINUATION" -- a continuation of an in-progress EAP conversation                                                                             |
| User-Id                   | After the RAD-Series Server parses the NAI (userid@realm), it assigns the userid value to this attribute.                                                                                                               |
| User-Realm                | After the RAD-Series Server parses the NAI (userid@realm), it assigns the realm value to this attribute.                                                                                                                |
| Time-of-Day               | A string containing the time of day the request was received. It uses a 24 hour clock in hh:mm format.                                                                                                                      |
| Day-Of-Week               | An integer representing the day of the week the request was received, where 0 represents Sunday and 6 represents Saturday.                                                                                               |
| Date-Time                 | A string containing the date and time the request was received. It uses a 24 hour clock in yyyy:mm:dd:hh:mm format.                                                                                                      |
Calling Decision Files

Once policies are stored in decision files, call the decision files at the appropriate points in the `radius.fsm` file, `authfile`, or user profiles.

From `radius.fsm`

The `POLICY` action should be called in the FSM whenever you wish to use Advanced Policy functions, such as Dynamic Access Control. Use the `Xstring` parameter to pass a decision file name to the `POLICY` action. The `Xstring` value must be no more than 63 characters long.

```
Event POLICY Next-state Xstring=decisionfile://Filename
```

You must specify the decision file to use each time the `POLICY` action is called. If necessary, your group entries should also contain a `Decision` reply item to return the next event to the FSM.

---

**Note:** If the `POLICY` action occurs before the user’s profile is retrieved, reply items from the decision file are superseded by any duplicate attributes in a user profile. Conversely, if `POLICY` occurs after the user’s profile is retrieved, the user’s reply items will be superseded by the policy group reply items.

The `DAC.fsm` and `DNIS.fsm` files distributed with the RAD-Series Server already call the corresponding decision file at the appropriate point in the RAD-Series Server’s process. You need only make implementation-specific changes. See “Modifying the FSM for DNIS” on page 190 and “Modifying the FSM for DAC” on page 189 for details.

From `authfile`

Place a `Policy-Pointer` in a LDAP realm data store naming the full path to the decision file containing the group authorization policies. Enclose the pointer in double or single quotes. The `Policy-Pointer` string cannot be more than 63 characters long.

```
realm ProLDAP “comment”
{
    Policy-Pointer = “decisionfile://path-to-file”
    Directory . . .
}
```

The `POLICY` action will look for the first group entry in the decision file that matches the A-V pairs in a user request and reply accordingly.

From user profiles

In the default users file or realm files, place a `Policy-Pointer` as a check or reply item naming the full path to the decision file containing the group authorization policies. Enclose the pointer in double or single quotes. The `Policy-Pointer` string cannot be more than 63 characters long.

```
carl Password = carl, Policy-Pointer = “decisionfile://path-to-file”
or
```

---
fred Password = fred  
Policy-Pointer = "decisionfile://path-to-file"

The **POLICY** action will look for the first group entry in the decision file that matches the A-V pairs in a user request and reply accordingly. See “User/Realm policy” on page 143 for more details.

## Dynamic Access Control

Dynamic Access Control (DAC) enables you to provide different levels of network access to the same users depending on:

- Access periods
- Account and password expiration date and time

Dynamic Access Control utilizes three Interlink-specific attributes to check values in user requests:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time-of-Day</td>
<td>A string containing the time of day the request was received. It uses a 24 hour clock in \textit{hh:mm} format.</td>
</tr>
<tr>
<td>Day-Of-Week</td>
<td>An integer representing the day of the week the request was received, where 0 represents Sunday and 6 represents Saturday.</td>
</tr>
<tr>
<td>Date-Time</td>
<td>A string containing the date and time the request was received. It uses a 24 hour clock in \textit{yyyy:mm:dd:hh:mm} format.</td>
</tr>
</tbody>
</table>
Modifying the FSM for DAC

Do the following to modify radius.fsm to support Dynamic Access Control.

1. In a text editor, copy the contents of DAC.fsm, by default found in /etc/opt/aaa.
2. Open radius.fsm (in the same directory) and paste the contents of DAC.fsm over radius.fsm. Replace the complete text.
3. If you’re using a different decision file than the supplied DAC.grp decision file, change the CheckDAC state so that the POLICY action calls your DAC decision file. For example:
   
   ```
   CheckDAC:
   *.ACK POLICY AuthWait Xstring=decisionfile://DAC.grp
   ```
4. Save and close radius.fsm.

DAC Decision File

Edit the DAC.grp decision file to define your DAC policies. There are sample entries for most groups you will need. Modify each group to reflect your time-based policies. For example:

```  
# Daytime Access Check
if ( (Access-Group[0] = "daytime") &&
   ((Time-Of-Day[0] >= "06:00") && (Time-Of-Day[0] <= "20:00") ) )
{
   insert Reply-Message = "Daytime access allowed"
   exit "ACK"
}
```

**Note:** The Reply-Message reply item attribute may not be returned if the user is authenticated with a tunneled EAP method.

Comment out any condition you don’t need by placing a pound sign (#) before each line.

The last line should remain so any user that does not match one of the conditions will get rejected.

If you rename this file, edit radius.fsm so that the CheckDAC state Xstring parameter points to the correct filename.

Keep this file in the RAD-Series Server’s configuration directory, by default /etc/opt/aaa.
DNIS Routing

In a typical DNIS routing scheme, requests are handled according to the Calling Station-Id and Called-Station-Id attributes. The POLICY action matches the Calling-Station-Id and Called-Station-Id attribute values in the Access-Request to the conditions defined in the DNIS decision file and returns the matching policy group reply items and the FSM events Forward and Abandon.

The required events and states are defined in the DNIS.fsm file delivered with the RAD-Series Server.

Modifying the FSM for DNIS

Do the following to modify radius.fsm to support DNIS routing.

1. In a text editor, copy the contents of DNIS.fsm, by default found in /etc/opt/aaa.

2. Open radius.fsm (in the same directory) and paste the contents of DNIS.fsm over radius.fsm. Replace the complete text.

3. If you’re using a different decision file than the supplied DNIS.grp decision file, change the Start3 state so that the POLICY action calls your DNIS decision file. For example:

Start3:

*.*.AUTHEN POLICY Start4 Xstring=decisionfile://DNIS.grp
*.*.AUTH_ONLY POLICY Start4 Xstring=decisionfile://DNIS.grp
*.*.AUTHENTICATE POLICY Start4 Xstring=decisionfile://DNIS.grp
*.*.ACCT POLICY Start4 Xstring=decisionfile://DNIS.grp
*.*.LAS_ACCT POLICY Start4 Xstring=decisionfile://DNIS.grp

4. Modify the Start4 state so that Xstring points to the fully qualified domain name, IPv4 address or IPv6 address of the server to which you are forwarding requests and must be listed in the RAD-Series Server’s clients file. The clients file entry is needed to get the shared secret to use.

Start4:

*.*.Forward RAD2RAD Start4a Xstring=192.168.0.0

5. Save and close radius.fsm.
**DNIS Decision File**

Edit the `DNIS.policy` decision file to reflect your station-based access policies. For example, change the Calling-Station and Called-Station numbers in the Controlled Access condition:

```plaintext
# Controlled Access
if ( ( count(Calling-Station-Id[0]) > 0 ) &&
     ( Calling-Station-Id[0] = "7341234567" ) )
{
    exit "Forward"
}

if ( ( count(Called-Station-Id[0]) > 0 ) &&
     ( Called-Station-Id[0] = "7341236543" ) )
{
    exit "Forward"
}
```

You can enter additional conditions and attributes to this policy if your policies require that other conditions be met.

Comment out any condition you don’t need by placing a pound sign (#) before each line.

The last line should remain unchanged so it can authenticate any user that does not match one of the other conditions.

If you rename this file, edit `radius.fsm` so that the `Start3 state Xstring` parameter points to the correct filename.

Keep this file in the RAD-Series Server’s configuration directory, by default `/etc/opt/aaa`. 
Configuration Files

About Configuration Files

Some advanced features of the RAD-Series Server cannot be configured through the Server Manager console. For example, if you want to define Advanced Policy, vendor-specific attributes, or logging behavior, you will need to manually edit the RAD-Series Server configuration files.

This section provides reference information for all the files that you may need to edit to maintain the RAD-Series Server configuration. Some of this information is also in the MAN pages distributed with the server. By default the man pages are located in /opt/share/aaa/man.

Throughout this section, required parameters are marked in bold face type and optional ones in a normal face. In addition, when a variable should be replaced with a specific value by the administrator, the variable will appear in an italic face. For example:

```
realm ProLDAP “comment”
{
    Directory “directory comment”
    {
        URL “ldap://192.168.3.8:389”
        SearchBase “ou=devision,dc=com”
    }
}
```

File Format

Entries

All configuration files consist of one or more entries. These entries include parameters that define a configuration item for the RAD-Series Server: a client, a user profile, a realm, and others.

A parameter (field) may contain one or more A-V pairs. See page 195 for a description of A-V pair syntax.

Entries that define grouped configuration objects use a block format:

```
block-name
{
    Parameter value
    Parameter “value string”
    ...
}
```

Enclose string values within single or double quotes if the value contains spaces or special characters other than underscore (_) and dash (-). There is no difference between using single or double quotes.
**Line Lengths**

The dictionary and vendors files have a maximum input line length of 255 characters. All other configuration files have a maximum input line length of 1023 characters. Anything exceeding the limit is processed as another line.

**Delimiters**

Fields within entries are delimited by whitespace (one or more spaces or tabs).

You may also use comma-space to delimit A-V pair lists in users files and .fsm files.

**Comment Lines**

Comment lines are indicated by a leading pound sign (`#`) character. The RAD-Series Server ignores all comment lines, as well as empty lines and entirely-blank lines. All lines are counted for the purpose of reporting errors, warnings, or changes. The Server Manager removes all the comment lines when making changes to a file.

**File Location**

By default, configuration files are located in:

```
/etc/opt/aaa
```

MAN pages are located in:

```
/opt/share/aaa/man
```
Commonly Used Files

The configuration files you'll most commonly work with are:

- **aaa.config** defines all RAD-Series Server properties.
- **authfile** defines realm datastores.
- **clients** defines client attributes and shared secret.
- **decision files** contain advanced policy information for user authorization and session control based on any logical group that can be defined with attribute-value (A-V) pairs. See “Using Advanced Policy” on page 140 for information about creating decision files.
- **dictionary** defines all attributes and values that may be used to build A-V pairs recognized by the RAD-Series Server. These A-V pairs convey information in requests and responses. This file also contains definitions for all the authentication types that the server recognizes.
- **EAP.authfile** defines realm authentication actions.
- **las.conf** defines Local Authorization Server behavior. It enables session tracking and specifies some session timing values.
- **log.config** defines accounting message logging behavior.
- **radius.fsm** is the Finite State Machine table. You can edit this to reorder processing steps or call custom plug-ins.
- **realm (.users)** files contain user profile entries, including check/deny and reply items. Realm files are sometimes referred to as .users files, because they contain profiles for users in a single realm and may be given any descriptive name, such as the realm name. All realm files **must** have the extension .users.
- **users** defines user profiles which can be used for exceptions to the normal realm based configuration. The default users file contains only the test_user entry after an initial installation.
- **vendors** contains optional entries for vendor names and numbers and it maps external attributes to and from vendor-specific attributes.

**Note:** The **dictionary, vendors, radius.fsm and log.config** files cannot be edited with the Server Manager; they must be manually-edited. Furthermore, all the files are read once at RAD-Series Server startup time and only **log.config** is re-read when the server receives a HUP signal.
Attribute-Value Pairs

The RAD-Series Server sends information in terms of attributes. When a message is exchanged among access devices and servers, one or more attributes and values are sent pairwise as an attribute-value pair (A-V pair).

\[ \text{attribute} = \text{value} \]

Attributes are defined to be one of the following value types: IPv4 address, IPv6 address, string, vendor, tag string, tag integer, date, integer, string, octet, short, IPv6 prefix and interface-id values. The attribute may take any of the supported, legal values defined for it in the dictionary file.

The RAD-Series Server supports most standard RADIUS attributes for session control and provisioning. Attribute names and their enumerated values are defined in the dictionary file. See the RADIUS RFC documents (2865, 2866, 2867, 2868, 2869) for a description of the attributes.

\[ \text{Note:} \text{ The Reply-Message attribute is not supported as a reply item for users in EAP PEAP and EAP TTLS realms.} \]

This section describes Interlink-specific configuration, RADIUS and session attributes with the files where they are most likely to be used.

Attribute-Value Pair Syntax (realm, users and .fsm)

When specifying A-V pairs in a realm file, users file or .fsm file entry, you should put a space before and after the equals (=) or not equal (!=) operator. Some other formats will work but are not guaranteed to be supported in future versions. An example is:

Simultaneous-Use = 3

Within a list of A-V pairs, A-V pairs are delimited by commas.

User-Name = msmith, Password = nopass, NAS-IP-Address = 192.168.6.59

Reply item A-V pairs in a .users file are listed on separate, indented lines. Put a comma after each line, except for the last in the list:

User-Name = msmith, Password =pass, NAS-IP-Address = 192.168.6.59
   Session-Timeout = 60, 
   Idle-Timeout = 15

String values must be enclosed by single quote or double quote characters if they contain spaces or special characters other than underscore (_) and dash (-). There is no difference between using single or double quotes. Otherwise, the quotation marks are optional:

Deny-Message = “Access Denied”

Deny-Message = Access_Denied
IPv4 address values use the common dotted-quad notation.

NAS-IP-Address = 10.11.0.9

IPv6 address values use the customary representation of groups of 16-bit hexadecimal values separated by colons ():

NAS-IPv6-Address = 2001:abc::123

**Date Attribute Value Formats**

Date type attributes can be entered in many formats. The rules are:

- When configuring a date attribute value, the values represent local time unless a “UTC” is appended to the time value string, in which case the values are interpreted as UTC.
- The “UTC” is case-insensitive.
- The “UTC” can immediately follow the hh:mm:ss, or can be placed after a delimiter.
- If the optional hh:mm:ss are not specified, the “UTC” can be placed immediately after the yyyy-mm-dd or mm/dd-yyyy, or can be placed after a delimiter.
- The delimiters are space “ “, dash “-“, slash “/”, and colon “:”.
- The value must be enclosed in quotes if it contains a space, otherwise quotes are optional.
- Spaces are the only allowed delimiters which may precede or follow the value.

**Format:** mmm-dd-yyyy HH:MM:SS UTC or yyyy-mm-dd HH:MM:SS UTC

- ‘mmm’ is a three character month abbreviation (Jan, Feb, Mar, etc.).
- ‘mm’ is the two digit month (1-12).
- ‘dd’ is the day (1 to 31).
- ‘yyyy’ is the year expressed as four digits (2011).
- ‘HH’ is the two digit hour.
- ‘MM’ is the two digit minutes.
- ‘SS’ is the two digit seconds.
- “UTC” is an optional field that will override the default, which is the local time zone.
- The ‘HH:MM:SS’ is optional, if not present HH:MM:SS defaults to 00:00:00.

The following are valid date values:

Expiration = "Apr 17 2010"
Expiration = "Apr 18 2010 UTC"
Expiration = Apr-19-2010UTC
Expiration = "Apr-19-2010 10:32:59"
Expiration = "Apr-09-2010 10:32:59 utc"
Expiration = "2010-04-05 0:0:0"
Expiration = 2010-03-16
Expiration = 2010-03-17UTC
Expiration = 2010-03-18/UTC
Expiration = 2010-03-15/01:02:03
Expiration = 2010-03-15/04:05:06utc
Expiration = 2010-03-15/04:05:07/utc
Expiration = "2010-04-05 0:0:1 UTC"
Expiration = "2010-04-05 0:0:2utc"
Expiration = "2010-04-05 0:0:3 UTC"
Expiration = "2010-04-05 0:0:3 UTC"
The following example is a syntactically valid A-V pair list:
Password = “rock”, Service-Type = “Framed”, Reply-Message = “OK”

The following examples are not syntactically valid A-V pair lists since the attributes are not separated by both a comma and a space:
Password="rock"Service-Type="Framed"Reply-Message="This is not OK"
Password = rock Service-Type = Framed Reply-Message = This is not OK

**Tagged Attributes**

A RAD-Series Server message may include multiple attributes that are tagged to organize them into defined groups. Depending on its capabilities, a client or server will selectively use one set of tagged attributes. Tagged attributes may be used as check or reply items.

Tagged attributes follow the syntax:

**Attribute = :Tag:Value**

*Attribute* is the attribute.

*Tag* is a unique integer (in the range 0-31) that provides a means of grouping attributes which refer to the same tunnel.

*Value* is the attribute value (in that set). A string value containing white space must be enclosed by double or single quotes:
Tunnel-Assignment-Id = :2:”Hello World”

For example, an Access-Accept may contain several different tunnel definitions as tagged attribute sets. Tunnel-Type = :1:PPTP indicates that PPTP is the Tunnel-Type in attribute set 1, which defines one type of tunnel that might be established for a user. A client which supports tagged attributes can selectively define the tunnel by using only the values belonging to one attribute set.
aaa.config

The `aaa.config` file contains user-defined entries for RAD-Series Server properties. These entries override the server’s built-in defaults.

All entries are delimited by whitespace (tabs or spaces).

If a value contains spaces, use single or double-quote characters to enclose the value.

Including Files

You can include configuration data in multiple text files and load them at RAD-Series Server startup. For each text file, add a one line entry to the `aaa.config` file that follows the format:

```
include filename
```

If `filename` specifies a relative path, the RAD-Series Server will look for the file in the configuration directory.

Server Variable Syntax

RAD-Series Server variables override the server’s built-in defaults. Those that can be configured on the Server Properties pages in the Server Manager will be noted

To add a server variable, enter a line in `aaa.config` for:

```
variable = value
variable value
```

Server variables are loaded into memory when the RAD-Series Server starts. Restart the server if you change server variables in the `aaa.config` file.

Any space or tab characters before the variable or surrounding the equal sign character are ignored. The equal sign is optional.
### General Server Properties

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authenticate_as_computer (boolean)</td>
<td>If enabled (Yes), the RAD-Series Server will strip “host/” from the EAP-Identity sent by Microsoft clients configured to authenticate as computer on a wireless connection. When using TLS authentication, the remaining string is compared to the selected “Client User Name Attribute” field in the client certificate. When using PEAP/MSCHAPv2 authentication, the remaining string is used as the inner-realm userid. The default value is Enabled (Yes). Server Manager property: <strong>Microsoft Host-Based Authentication</strong></td>
</tr>
<tr>
<td>avpair_checking (boolean)</td>
<td>Whether or not the RAD-Series Server should perform sanity checks of A-V pairs in messages by checking to see if the flags indicate a valid A-V pair, and if it's a string type A-V pair, whether the string’s use count is valid and print the diagnostic information. Values are on or off. This is for diagnostic purposes only and should not be used in production. The default value is off.</td>
</tr>
<tr>
<td>cwd (string)</td>
<td>Changes the current working directory of the RAD-Series Server to the specified path. This will be the location of any core files if the server aborts. This allows for overriding the radiusd –c option. The default value is the -c option value. If no -c option was used, then the default is the current working directory of the shell that started radiusd.</td>
</tr>
<tr>
<td>default_reply_holdtime (integer)</td>
<td>Number of seconds the RAD-Series Server holds a request after replying to it in case a retransmission of the response is necessary. The value should be twice the default retransmission period of the access devices involved. This does not apply to packets that are forwarded to another server. A value of zero invokes special behavior in which the REPLY AATV does not change the hold time for a request. This would cause all received authentication or accounting requests to be held for the full TTL (time-to-live), regardless of how short or how long the request took before being replied to. <strong>Note:</strong> Using the special value of zero or using a hold time greatly in excess of the retransmission policy of a NAS may cause the authentication and accounting queues to grow excessively large impacting performance. Refer to the global_acct_q.limit and global_auth_q.limit variables. Tailoring of this value should be influenced by the total and holding values reported on a per-request basis. The default value is 6 seconds. Server Manager property: <strong>Hold Replies</strong></td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>default_retry_limit (integer)</td>
<td>Maximum number of retransmissions allowed before a RETRY event occurs (a RETRY event is similar to a TIMEOUT event and is handled by the built-in default FSM table). The purpose of this is to catch an authentication request and perform some action when a certain number of retransmissions from an access device occur. The default is 0 and no limits are imposed. In particular, it may be useful to have a primary authentication RAD-Series Server deny access (using the FAIL AATV) before a backup server starts to authenticate, allowing the backup server to backup just the primary and not the whole AAA system. The default value is 0. Server Manager property: <strong>Global Retry Limit</strong></td>
</tr>
<tr>
<td>default-source-ipv4-address (ipv4 address)</td>
<td>Sets the default IPv4 address to use as the source IPv4 address when proxying an Access-Request or Accounting-Request. This parameter can be overridden by the &quot;srcrip&quot; parameter in the clients file. The default value is '0.0.0.0' which means the operating system will assign the source IP address. Server Manager property: <strong>Default local IPv4 address for IPv4 proxy socket</strong></td>
</tr>
<tr>
<td>default-source-ipv6-address (ipv6 address)</td>
<td>Sets the default IPv6 address to use as the source IPv6 address when proxying an Access-Request or Accounting-Request. This parameter can be overridden by the &quot;srcrip&quot; parameter in the clients file. The default value is '[:]' which means the operating system will assign the source IP address. Server Manager property: <strong>Default local IPv6 address for IPv6 proxy socket</strong></td>
</tr>
<tr>
<td>dns_address_aging (integer)</td>
<td>The base value (in seconds) used to periodically refresh DNS entries. To ensure that all the client entries don’t expire at once, a designed-in randomness adds zero, fifteen, thirty, or forty-five minutes to the base value to determine when a DNS entry should be refreshed. The default value is 3600 (1 hour). Server Manager property: <strong>DNS Refresh Interval</strong></td>
</tr>
<tr>
<td>dns_address_window (integer)</td>
<td>When a DNS entry for a configured client expires (needs refreshing), all other clients that will be refreshed within the specified number of seconds are refreshed immediately. The default value is 60 seconds. Server Manager property: <strong>DNS Refresh Time Frame</strong></td>
</tr>
<tr>
<td>dns_max_aliases (integer)</td>
<td>Maximum number of aliases per client. The default value is 3.</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>global_acct_q.hold</td>
<td>The number of additional seconds each accounting request should be held after it has been replied to. When this time expires, the request is released. This hold time allows the RAD-Series Server to detect and respond to duplicate requests. You should specify a value that is twice the retransmission interval configured on your access device. The default value is 0 seconds.</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: <strong>Hold Accounting Requests</strong></td>
</tr>
<tr>
<td>global_acct_q.limit</td>
<td>The maximum number of simultaneous accounting requests to be held on the accounting queue at any one time. This includes pending requests in progress plus requests which have been replied to but whose <strong>reply-holdtime</strong> has not yet expired. When this limit is reached, new requests are discarded (not replied to) with a message in the logfile. The same equation used for sizing the <strong>global_auth_q.limit</strong> may also be used for <strong>global_acct_q.limit</strong>. The default value is 40,000.</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: <strong>Max. Accounting Requests</strong></td>
</tr>
<tr>
<td>global_auth_q.hold</td>
<td>The number of additional seconds each authentication request should be held after it has been replied to. When this time expires, the request is released. This hold time allows the RAD-Series Server to detect and respond to duplicate requests. You should specify a value that is twice the retransmission interval configured on your access device. The default value is 0 seconds.</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: <strong>Hold Authentication Requests</strong></td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>global_auth_q.limit (integer)</td>
<td>The maximum number of active authentication requests to be held on the auth queue at any one time. This includes pending requests in progress plus requests which have been replied to but whose reply-holdtime has not yet expired. When this limit is reached, new requests are discarded (not replied to) with a message in the logfile. The auth queue must be sized correctly in order to buffer the arrival rate of access requests. If the arrival rate of requests is relatively steady then you can size the queue and hold time as follows: [ \text{global_auth.q.limit}/\text{default_reply_holdtime} &gt; \text{transaction rate} ] For example, if ( \text{global_auth.q.limit}=1000 ), ( \text{default_reply_holdtime}=5 ), and ( \text{transaction rate}=100 ) authentications/second, then [ 1000/5 = 200 \implies 200 &gt; 100 ] For the first five seconds the queue is filling up to 500 authentication requests. From that point on the requests are still arriving at 100/second, but the oldest requests are being released at 100/second. Now, suppose ( \text{global_auth.q.limit}=1000 ), ( \text{default_reply_holdtime}=5 ), and ( \text{transaction rate}=250 ) authentications/second, then [ 1000/5 = 200 \implies 200 &lt; 250 ] For the first four seconds the queue is filling up to 1000 authentication requests. For the fifth second another 250 requests arrive, but there is no room in the queue. No requests will be released until the end of the fifth second, since that is the hold time. Either the ( \text{global.auth.q.limit} ) must be increased, or the ( \text{default_reply_holdtime} ) must be decreased. Note: When the authentication queue limit is exceeded, the RAD-Series Server stops responding to the radcheck command. The default value is 40000. Server Manager property: <strong>Max. Authentication Requests</strong></td>
</tr>
<tr>
<td>ipv6_enabled (boolean)</td>
<td>Enables the IPv6 support in the RAD-Series Server. When IPv6 is disabled the server will ignore any IPv6 configurations except for LDAP. See “IPv6 Operation” on page 267 for more information. The default value is off. Server Manager property: <strong>Enable IPv6 Communications</strong></td>
</tr>
<tr>
<td>list_copy_limit (integer)</td>
<td>For customized RAD-Series Server configurations that accumulate A-V pairs or generate large responses. The default value is 512.</td>
</tr>
<tr>
<td>compress-logfile (integer)</td>
<td>This parameter indicates if the old logfile should be compressed when rolled over (by date or by size) to a new logfile. Enabled (Yes) is the default. Server Manager property: <strong>Logfile Compression</strong></td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>maximum-output-file-size (integer)</td>
<td>The maximum size in bytes of the RAD-Series Server log file and the accounting log file. The minimum value for this parameter is 65536; the maximum is 2147483647. When a log file reaches this size, it is &quot;rolled over&quot;. For example, if the current log file is logfile.2010120103, then it is renamed to logfile_part01.2010120103 and the new log file is named logfile_part02.2010120103. See &quot;DESCRIPTION roll logfile&quot; on page 116 and &quot;DESCRIPTION roll stream&quot; on page 116 for more details of the file naming. The default value is 2147483647. Server Manager property: <strong>Maximum Log File Size</strong></td>
</tr>
<tr>
<td>ourhostname (string)</td>
<td>This variable is no longer used. It is accepted but ignored. The functionality of this parameter has been superseded by the 'ipaddr' variable in the radius_socket block, the default-ipv4-source-address, the default-ipv6-source-address, and the 'srcip' in the clients file.</td>
</tr>
<tr>
<td>proxy_udp_recv_buffer_size (integer)</td>
<td>The requested UDP buffer size for response packets to proxied requests. The minimum value is 8192 bytes; the maximum is 6388608 bytes. The default value is 0 which lets the operating system set the UDP receive buffer size. Note: The operating system may not honor the requested buffer size. A logfile message will display the actual buffer size allocated by the operating system. Server Manager property: <strong>UDP receive buffer size for proxy sockets</strong></td>
</tr>
<tr>
<td>radius_log_fmt (string)</td>
<td>This variable overrides the radiusd -l option to specify the logfile name format string to be used. The default value is &quot;logfile.%Y%m%d&quot;</td>
</tr>
<tr>
<td>recv_buffer_size (integer)</td>
<td>The maximum size in bytes for an individual inbound RADIUS message. The minimum value is 4096; the maximum is 65535. The default value is 16536. This property is primarily intended for supporting an access client that might transmit very large packets. Server Manager property: <strong>Max. Receive Message Size</strong></td>
</tr>
<tr>
<td>send_buffer_size (integer)</td>
<td>The maximum size in bytes for an outbound RADIUS packet. The minimum value is 4096. The default value is 16536. This property is primarily intended for supporting a customized RAD-Series Server configuration that might transmit very large packets. Limiting this variable to be the UDP MTU for the network will prevent excessively large packets from being forwarded (or replied to) in certain circumstances. Server Manager property: <strong>Max. Send Message Size</strong></td>
</tr>
</tbody>
</table>
### Server Tracking Properties

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>send_proxy_action</td>
<td>Controls the sending of the MERIT Proxy-Action A-V pair in RADIUS replies or packets forwarded through the RAD-Series Server to another RADIUS server. Valid values are on or off. The default value is off.</td>
</tr>
<tr>
<td>users_file_maxlen</td>
<td>Set the maximum line length for reading the users file and/or realm files. The values may range from 1024 to 16534 characters per line. The default value is 1024.</td>
</tr>
<tr>
<td>log_forwarding</td>
<td>Turns on or off logging of packets forwarded through the RAD-Series Server to another RADIUS server. This allows finer logging detail when tracking problems, at the expense of increased log file size. The variable can occur multiple times to select the set of options desired. Valid options are: • on - Turns on the logging of forwarded packets • off - Turns off all logging of forwarded packets • +digest - log sent forwarding digest turned on • –digest - log sent forwarding digest turned off • +dump - printing of packet contents in hexadecimal is turned on • –dump - printing of packet contents in hexadecimal is turned off • +vector - log initial forwarding digest turned on • –vector - log initial forwarding digest turned off • clear - is equivalent to –digest plus –dump The default value is off.</td>
</tr>
<tr>
<td>log_generated_request</td>
<td>Turns on or off the logging of internally generated packets when they are created and when they reach their end-state. It is useful for a customized RAD-Series Server configuration that produces accounting requests based on internal state transitions rather than on externally delivered requests. Valid values are on or off. The default value is on.</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>packet_log</td>
<td>This variable matches a current request with an original request, which may occur when logging certain attributes in a request log. It is useful for tracking situations where a remote RAD-Series Server is responding with incorrect values and to investigate if an AATV is corrupting the current request. The variable can occur multiple times to select the set of options desired. Valid options are:</td>
</tr>
<tr>
<td></td>
<td>• default - sets +current and +original</td>
</tr>
<tr>
<td></td>
<td>• clear (or none) - removes all options</td>
</tr>
<tr>
<td></td>
<td>• +abort - Turn on abort and core-dump if there is a mismatch</td>
</tr>
<tr>
<td></td>
<td>• –abort - Turn off abort and core-dump if there is a mismatch</td>
</tr>
<tr>
<td></td>
<td>• +both (or +comp) - Turn on comparison of A-V pairs if +current and +original are set</td>
</tr>
<tr>
<td></td>
<td>• –both (or –comp) - Turn off comparison of A-V pairs</td>
</tr>
<tr>
<td></td>
<td>• +current (or +cur) - Turn on report only from the modified request</td>
</tr>
<tr>
<td></td>
<td>• –current (or +cur) - Turn off report only from the modified request</td>
</tr>
<tr>
<td></td>
<td>• +original (or +orig) - Turn on report only from original request</td>
</tr>
<tr>
<td></td>
<td>• –original (or –orig) - Turn off report only from original request</td>
</tr>
<tr>
<td></td>
<td>The default value is +current and +original</td>
</tr>
</tbody>
</table>
This variable enables (or disables) certain reports produced by the radcheck command. The variable can occur multiple times to select the set of options desired. Valid options are:

- default - Turns on +queues and +mf.
- clear - Turns off all the radcheck options and clears the authentication queue counters.
- none - Turns off all the radcheck options.
- reset - Clears the authentication queue counters.
- +mf - Show malloc and free statistics.
- -mf - Do not show malloc and free statistics.
- +packets - Show statistics about the number of octets/packets received, replied, forwarded, replies received, and redone.
- -packets - Do not show statistics about the number of octets/packets received, replied, forwarded, replies received, and redone.
- +queues - Show authentication and accounting queue information such as: number of unique requests, number of queue overflows, number of duplicate requests. If the number of accounting requests greatly exceeds the number of authentication requests and the NAS is not sending interim accounting, then a NAS/network configuration error is possible.
- –queues - Do not show authentication and accounting queue information.
- +timeouts - Show various timeout counters.
- –timeouts - Do not show various timeout counters.

The default value is +queues and +mf.

</table>
SNMP Server Properties

The SNMP support uses the block format to define variables. This block is read at RAD-Series Server startup time, and, unlike most of the other aaa.config blocks, is not re-read when the server processes a HUP signal. The block format looks like this:

```plaintext
iaaa.SNMP
{
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reply_check</td>
<td>This variable specifies which attributes to check in a reply to ensure they are the same as in the forwarded request. Options allow you to specify the action to take when a mismatch occurs. The variable can occur multiple times to select the set of options desired. Valid options are:</td>
</tr>
<tr>
<td>first</td>
<td>Turn on check only the first match, turns off all</td>
</tr>
<tr>
<td>all</td>
<td>Turn on check all attributes for matches, turns off first</td>
</tr>
<tr>
<td>default</td>
<td>Clears all options, sets first and clears the list of attributes to check</td>
</tr>
<tr>
<td>none</td>
<td>Clears the list of attributes to check</td>
</tr>
<tr>
<td>clear</td>
<td>Clears all options and sets first</td>
</tr>
<tr>
<td>+abort</td>
<td>Turn on abort and core-dump if a check fails</td>
</tr>
<tr>
<td>–abort</td>
<td>Turn off abort and core-dump if a check fails</td>
</tr>
<tr>
<td>+dump</td>
<td>Turn on logging of the offending packet (in hex)</td>
</tr>
<tr>
<td>–dump</td>
<td>Turn off logging of the offending packet</td>
</tr>
<tr>
<td>+ignore</td>
<td>Turn on ignoring of responses which have a mismatch</td>
</tr>
<tr>
<td>–ignore</td>
<td>Turn off ignoring of responses which have a mismatch</td>
</tr>
<tr>
<td>+verbose</td>
<td>Turn on logging of good and bad values of each attribute</td>
</tr>
<tr>
<td>–verbose</td>
<td>Turn off logging of good and bad values of each attribute</td>
</tr>
<tr>
<td>&lt;Attribute-name&gt;</td>
<td>- Add this specific attribute to list of checks</td>
</tr>
</tbody>
</table>

The default value is none.
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled (boolean)</td>
<td>When Enabled is set to ‘on’, the RAD-Series Server will automatically check the server for an SNMP master agent to communicate with, and the server can be monitored by an SNMP workstation. When set to ‘off’, the server will not communicate with an SNMP master agent and cannot be monitored by an SNMP workstation. Valid values are on or off. The default value is off. Server Manager property: <strong>Enable SNMP Support</strong></td>
</tr>
</tbody>
</table>
## Certificate Path Server Properties

For the EAP-TLS, EAP-TTLS, and EAP-PEAP protocols you need to provide several files used for encryption and identification. The locations of these files is specified in the securities.path block. This block is read at RAD-Series Server startup time, and, unlike most of the other aaa.config blocks, is not re-read when the server processes a HUP signal. The block format looks like this:

```
security.paths
{
    Certificate-Path "<file_path>"
    Key-Path "<file_path>"
    CA-Path "<file_path>"
    Random-Path "<file_path>"
    CRL-Path "<file_path>"
    ECDSA-Certificate-Path "<file_path>"
    ECDSA-Key-Path "<file_path>"
    ECDHE-Parameter-Curve "<curve_name>"
    Cert-Name-Attr "<attr_desc>"
    Tunneled-EAP-MTU-Reduction <value>
    SSL-Debug-Level <value>
}
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate-Path (string)</td>
<td>Full path to the RAD-Series Server RSA certificate in .pem or .cer format. The CA certificate for this server certificate MUST be present in the CA list file. To disable the RSA cipher suites, configure this variable as empty (&quot;&quot;). The default value is set based on the installation location and is by default set to: /etc/opt/aaa/security/rsa_cert.pem</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: <strong>Server Certificate Path</strong></td>
</tr>
<tr>
<td>Key-Path (string)</td>
<td>Full path to the file in .pem or .cer format that contains the private key used to generate the RAD-Series Server RSA certificate. This file cannot have a pass phrase or be encrypted. To disable the RSA cipher suites, configure this variable as empty (&quot;&quot;&quot;). The default value is set based on the installation location and is by default set to: /etc/opt/aaa/security/rsa_key.pem</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: <strong>Server Private Key Path</strong></td>
</tr>
<tr>
<td>CA-Path (string)</td>
<td>Full path to the Certificate Authority certificate for the client and server certificates. Used by the RAD-Series Server to authenticate client certificates. The CA certificate must be in .pem format. The default value is set based on the installation location and is by default set to: /etc/opt/aaa/security/ca_list.pem</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: <strong>Client Certificate Authority Path</strong></td>
</tr>
</tbody>
</table>
### Variable | Description
--- | ---
Random-Path (string) | Full path to the random seed used to generate encryption keys. The default value is set based on the installation location and is by default set to: 
/\texttt{etc/opt/aaa/security/random.rnd} 
Server Manager property: Random Seed Path

CRL-Path (string) | Full path to the Certificate Revocation List. This is used by EAP-TLS to identify certificates that are no longer valid and therefore the access will be denied. The default value is set based on the installation location and is by default set to: 
/\texttt{etc/opt/aaa/security/random.rnd} 
Server Manager property: Certificate Revocation List Path

ECDSA-Certificate-Path (string) | Full path to the RAD-Series Server ECDSA certificate in \texttt{.pem} or \texttt{.cer} format. The CA certificate for this server certificate MUST be present in the CA list file. To disable the ECC cipher suites, configure this variable as empty ("") or do not configure it at all. The default value is set based on the installation location and is by default set to: 
/\texttt{etc/opt/aaa/security/ecdsa_cert.pem}

ECDSA-Key-Path (string) | Full path to the file in \texttt{.pem} or \texttt{.cer} format that contains the private key used to generate the RAD-Series Server certificate. This file cannot have a pass phrase or be encrypted. To disable the ECC cipher suites, configure this variable as empty ("") or do not configure it at all. The default value is set based on the installation location and is by default set to: 
/\texttt{etc/opt/aaa/security/ecdsa_key.pem}

ECDHE-Parameter-Curve (string) | The name of the elliptic curve to use for generating the ECDH ephemeral key. To enable the ECDHE cipher suites, the ECDHE parameter curve must be configured. To disable the ECC cipher suites, configure this variable as empty ("") or do not configure it at all. A few of the many possible names are:
- secp256r1
- secp384r1
- secp521r1
The default value is "secp256r1".
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| Cert-Name-Attr (string)        | For TLS this identifies the attribute in the client certificate that the RAD-Series Server should verify is the same as the User-Name in the authentication request. If it does not match, the access will be denied. The default value is “Subject:CommonName”. The list of valid certificate attributes is:  
  • “Subject:CommonName”  
  • “SubjectAltName:RFC822Name”  
  • “Subject:EmailAddress”  
  • “CheckAllNameFields”  
  Server Manager property: **Client User Name Attribute** |
| Tunneled-EAP-MTU-Reduction (integer) | The number of bytes by which to reduce the Framed-MTU AVP value when a EAP-PEAP/EAP-TTLS inner (tunnel) request is created. EAP-PEAP and EAP-TTLS must have enough room in the outer packet to contain the inner (tunneled) EAP conversation plus any attributes (such as Reply-Message) that must be sent outside the tunnel during the exchange. This parameter specifies how much of the outer Framed-MTU value is reserved for these non-tunneled attributes when constructing an inner reply. A value of at least 100 appears to be required for EAP-PEAP/EAP-TLS. The minimum value is 0 and the maximum value is 512. The default value is 0  
  Server Manager property: **Tunneled EAP MTU Reduction** |
| SSL-Debug-Level (integer)      | The minimum RAD-Series Server debug level required so that SSL debug output is produced in the radius.debug file. A value of 0 disables SSL debug output. The minimum value is 0 and the maximum value is 4. The default value is 0  
  Server Manager property: **SSL Debug Level** |
**ProLDAP Connection Properties**

The ProLDAP support uses the block format to define variables. The block format looks like this:

```
aatv.ProLDAP
{
    variable value
    ...
}
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAP-Version (integer)</td>
<td>The version of the LDAP protocol to employ. If your LDAP server requires version 2 of the protocol, enter that number here. The default value is 3. Server Manager property: <strong>LDAP version</strong></td>
</tr>
<tr>
<td>Enable-Default-Conf (boolean)</td>
<td>Enables the OpenLDAP software to read its default configuration file, /etc/openldap/openldap.conf. This allows you to configure more of the OpenLDAP options. The default value is off. <strong>NOTE</strong>: Enable-Default-Conf configuration must precede any TLS-xxx configuration parameters.</td>
</tr>
<tr>
<td>Retry-Interval (integer)</td>
<td>Sets the number of seconds for the RAD-Series Server to wait before trying to reconnect to a LDAP directory server, when a realm has failover directory servers configured. The default value is 60 seconds. Server Manager property: <strong>Retry interval (seconds)</strong></td>
</tr>
<tr>
<td>Retry-Wait (integer)</td>
<td>Sets the number of seconds that the RAD-Series Server will wait before attempting to connect to the same failover LDAP server. When all failover directory servers configured for a realm are down, the RAD-Series Server will try to reconnect to one of the servers every time an access request is received. In that situation, this parameter guarantees that the software does not spend too much time in trying to reconnect those directory servers. The default value is 1 second. Server Manager property: <strong>Minimum wait before retry (seconds)</strong></td>
</tr>
<tr>
<td>Timeout (integer)</td>
<td>Sets the number of seconds that an LDAP connection will remain open when the RAD-Series Server has not been able to successfully perform any successful LDAP operation. This parameter allows better handling of the situation where the LDAP directory times out client connections. The default value is 60 seconds. Server Manager property: <strong>LDAP timeout (seconds)</strong></td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TCP-Timeout</td>
<td>Sets the number of 1/10 seconds that the RAD-Series Server will wait for an LDAP server when trying to establish the TCP connection. The default value is 30 (3 seconds). Server Manager property: Timeout for TCP connect (seconds)</td>
</tr>
</tbody>
</table>
| Debug           | Enables or disables OpenLDAP debugging. Output is written to the radius.debug file. The default is 0, disabled. A value of -1 maximizes LDAP debugging. See the OpenLDAP documentation for additional debug levels.  
**NOTE:** The OpenLDAP debugging only occurs if the RAD-Series Server debug has also been enabled.  
Server Manager property: OpenLDAP Debug |
| TLS-CACertDir   | Used if SSL is enabled for the connection to the LDAP servers. This is the path to a directory containing individual Certificate Authority files. This is used if there is no single TLS CA certificate file specified. There is no default value.  
**NOTE:** Use of SSL requires either TLS-CACertDir or TLS-CACertFile to be defined.  
Server Manager property: TLS CA certificate directory |
| TLS-CACertFile  | Used if SSL is enabled for the connection to the LDAP servers. The full path of a single file containing certificates for all the Certificate Authorities that clients will recognize. If defined, this variable will be used instead of the TLS CA certificate directory. There is no default value.  
**NOTE:** Use of SSL requires either TLS-CACertDir or TLS-CACertFile to be defined.  
Server Manager property: TLS CA certificate file |
| TLS-CertFile    | The TLS RAD-Series Server certificate file specifies the file that contains the certificate that the server will use. This parameter is necessary if any of the LDAP directories are configured to use SSL and require validation of the LDAP client certificate. There is no default value.  
Server Manager property: TLS certificate file |
| TLS-KeyFile     | The TLS RAD-Series Server private key file specifies the file that contains the private key that the server will use. This parameter is necessary if any of the LDAP directories are configured to use SSL and require validation of the LDAP client certificate. There is no default value.  
Server Manager property: TLS private key file |
RADIUS Listen Socket Properties

The RADIUS listen sockets are configured as a set of one or more `radius_socket()` configuration blocks, with these parameters:

```plaintext
radius_socket
{
    ipaddr <ipaddress>       # Required, IPv4 or IPv6 address
    acctport <port#>         # One or both of the ports
    authport <port#>         # must be specified
    acct_udp_recv_buffer_size<bufsize> # Optional, else use OS default
    auth_udp_recv_buffer_size<bufsize> # Optional, else use OS default
}
```

**Note:** The parameter names ("ipaddr", "authport", etc) are case insensitive. The values for `ipaddr` are also case insensitive. The name of the block "radius_socket" is, as are all curly brace block names, case sensitive.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipaddr</td>
<td>The IP address can be an IPv4 specific address, an IPv6 specific address, the IPv4 ANY address (0.0.0.0), or the IPv6 ANY address (::). The IP address may optionally be enclosed in square brackets. This parameter is required. If the IPv4 ANY address is specified, the RAD-Series Server will listen on all IPv4 interfaces. If the IPv6 ANY address is specified, the server will listen for IPv4 and IPv6 messages on all interfaces. There is no default value. Server Manager property: <strong>IP Address</strong></td>
</tr>
</tbody>
</table>
| acctport     | Sets the UDP port number to receive accounting requests on. The minimum value is 0 and the maximum value is 65535. In order to use the radius_socket block, you must specify at least one of the two ports. There is no default value. 

If acctport is configured with the special value of zero, the RAD-Series Server will execute a hierarchy of steps to determine the accounting listen port:

- If “-q acctport” is specified on the startup command, use that value, else
- If the environment variable RAD_ACCT_PORT is defined, use that, else
- If a RADIUS accounting port is configured in the /etc/services file, use that, else
- Use 1813, as defined by the RADIUS RFC.

If acctport is not configured, the server will not open an accounting listen socket for the given <ipaddress>.  
Server Manager property: **Accounting port** |
authport (integer)

Sets the UDP port number to receive authentication requests on. The minimum value is 0 and the maximum value is 65535. In order to use the radius_socket block, you must specify at least one of the two ports. There is no default value.

If authport is configured with the special value of zero, the RAD-Series Server will execute a hierarchy of steps to determine the accounting listen port:

1. If "-p authport" is specified on the startup command, use that value, else
2. If the environment variable RAD_AUTH_PORT is defined, use that, else
3. If a RADIUS auth port is configured in the /etc/services file, use that, else
4. Use 1812, as defined by the RADIUS RFC.

If authport is not configured, the server will not open an authentication listen socket for the given <ipaddress>.

Server Manager property: Authentication port
## Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| acct_udp_recv_buffer_size (integer) | The requested size in bytes that the operating system will use to buffer inbound RADIUS UDP packets received on the accounting port. This parameter allows the increasing of the amount of buffering that may be needed to handle a peak load. Increasing the buffering too much could have undesired affects.  

**Note:** The operating system may not honor the requested buffer size. A logfile message will display the actual buffer size allowed by the operating system.  

The minimum value is 8192 and the maximum value is 8388608. There is no default value. If this parameter is not specified or is specified with a value of zero, the value used is the operating system's UDP default buffer size.  

Server Manager property: **Accounting port UDP receive buffer size**                                                                                                                                                                                                                   |
| auth_udp_recv_buffer_size (integer) | The requested size in bytes that the operating system will use to buffer inbound RADIUS UDP packets received on the authentication port. This parameter allows the increasing of the amount of buffering that may be needed to handle a peak load. Increasing the buffering too much could have undesired affects.  

**Note:** The operating system may not honor the requested buffer size. A logfile message will display the actual buffer size allowed by the operating system.  

The minimum value is 8192 and the maximum value is 8388608. There is no default value. If this parameter is not specified or is specified with a value of zero, the value used is the operating system's UDP default buffer size.  

Server Manager property: **Authentication port UDP receive buffer size**                                                                                                                                                                                                                         |
**DHCP Server Properties**

The DHCPv4 support uses the block format to define variables. The block format looks like this:

```
aatv.DHCP
{
    dhcp-enabled value
    dhcp-server-name value
    dhcp-server-ip-address value
    dhcp-server-port value
    dhcp-relay-port value
    send-user-class-option value
    dhcp-client-hardware-type value
    initial-retransmission-interval value
    max-retransmission-interval value
    max-number-of-dhcpdiscover-retransmissions value
    max-number-of-dhcprequest-retransmissions value
    max-dhcp-msg-len value
    send-maximum-dhcp-message-size-option value
}
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dhcp-enabled (string)</td>
<td>If Yes, it enables the DHCP Relay function. The default is No. Server Manager property: Enable DHCP Support</td>
</tr>
<tr>
<td>dhcp-server-name (string)</td>
<td>Specifies the fully qualified domain name of the DHCPv4 server to use. You can configure this variable or the dhcp-server-ip-address but one is required. There is no default value. Server Manager property: DHCP Server Name</td>
</tr>
<tr>
<td>dhcp-server-ip-address (IP address)</td>
<td>Specifies the IPv4 address of the DHCPv4 server to use. You can use this variable or the dhcp-server-name but one is required. This variable takes precedence over dhcp-server-name. There is no default value. Server Manager property: DHCP Server IP Address</td>
</tr>
<tr>
<td>dhcp-server-port (integer)</td>
<td>The UDP port on the DHCP server to which DHCP requests are sent. The default value is 67. Server Manager property: DHCP Server Port</td>
</tr>
<tr>
<td>dhcp-relay-port (integer)</td>
<td>The UDP port on the RAD-Series Server at which DHCP responses are received. The default value is 67. Server Manager property: DHCP Relay Port</td>
</tr>
<tr>
<td>dhcp-client-hardware-type (integer)</td>
<td>Value passed to the DHCP server to indicate hardware type. Options are: 0 (NONE) or 1 (ETHERNET). The default value is 1. Server Manager property: Client Hardware Type</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>initial-retransmission-interval (integer)</td>
<td>Interval, in seconds, before the initial retransmission of a request to the DHCP server. The RAD-Series Server will double the retransmission interval for each subsequent retransmission. The default value is 4 seconds. Server Manager property: <strong>Initial Retransmission Interval</strong></td>
</tr>
<tr>
<td>max-retransmission-interval (integer)</td>
<td>The maximum interval in seconds at which the RAD-Series Server retransmits DHCP requests. The default value is 60 seconds. Server Manager property: <strong>Maximum Retransmission Interval</strong></td>
</tr>
<tr>
<td>max-number-of-dhcpdiscover-retransmissions</td>
<td>The maximum number of retransmissions RAD-Series Server makes when acknowledging IP address assignments from the DHCP Server. The default value is 2. Server Manager property: <strong>Maximum Discover Retransmissions</strong></td>
</tr>
<tr>
<td>max-number-of-dhcprequest-retransmissions</td>
<td>The maximum number of retransmissions RAD-Series Server makes when requesting IP address assignments from the DHCP Server. The default value is 2. Server Manager property: <strong>Maximum Request Retransmissions</strong></td>
</tr>
<tr>
<td>max-dhcp-msg-len (integer)</td>
<td>The maximum size in bytes of messages that can be received from the DHCP server. The default value is 1500. Server Manager property: <strong>Maximum DHCP Message Length</strong></td>
</tr>
<tr>
<td>send-maximum-dhcp-message-size-option (boolean)</td>
<td>If Yes, send the Maximum-DHCP-Message-Size option to the DHCP server (required by some DHCP servers) in the Discovery message. If No, do not send this option. The default value in No. Server Manager property: <strong>Send Maximum DHCP Message Size Option</strong></td>
</tr>
<tr>
<td>send-user-class-option (boolean)</td>
<td>Specifies which attribute in the DHCP message will carry the IPv4 address pool name. If Yes, the pool name will be sent in the User-Class option. If No, the pool name will be sent in the Vendor-Class-Identifier option. The default value is No. Server Manager property: <strong>Send User Class Option</strong></td>
</tr>
</tbody>
</table>
**Tunneling Properties**

The tunneling support uses the block format to define variables. The block format looks like this:

```plaintext
aatv.Tunneling
{
  variable value
  ...
}
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| NO_HINT (String) | This parameter specifies what the RAD-Series Server should do with tunneling attributes configured as reply items for a user entry. There can only be one NO_HINT variable specified. The following entries are valid:  
  NO_HINT Return-Configured-Tunnel-Attributes  
  NO_HINT Return-No-Tunnel-Attributes  
  NO_HINT Reject-Access-Request  
  The default will return configured tunnel attributes.  
  You cannot control how the server will resolve configured attributes and hints. When tunneling hints exist in an Access-Request, attribute values will be returned to the client as follows:  
  • Configured attributes will be returned if all hints match configured values.  
  • If some or no hints match configured attributes, the hints and attributes will be consolidated. If there are conflicting attribute values, the configured value will be used.  
  • If no configured attributes exist, no attributes will be returned.  
  Server Manager property: **Handling requests with no tunneling hints** |
| HINTS | This parameter specifies the behavior when the RAD-Series Server receives an Access-Request that contains Tunnel Hint attributes. The values are:  
  “HINTS Accept”: Accept and process the received tunnel attributes.  
  “HINTS Discard”: Discard the received tunnel attributes. Processing of the Access-Request proceeds as if the tunneling attributes were never present.  
  If no value is configured, the default is Accept.  
  Server Manager property: **Handling requests with tunneling hints** |
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| Tagged-VSA-Hints               | This parameter specifies the behavior when the RAD-Series Server receives an Access-Request that contains VSA Tunnel Hint attributes. The options are:  
  Accept: Accept and process the received VSA tunnel attributes.  
  Discard: Discard the received tunnel attributes. Processing of the Access-Request proceeds as if the tunneling VSAs were never present.  
  Reject: Fail the authentication by sending an Access-Reject  
  If no value is configured, the default is Accept  
  Server Manager property: Handling requests with VSA tunneling hints                                                                                                                                                                                                                       |
| Tunnel-Password-Requires-Message-Authenticator | This parameter indicates if a Message-Authenticator attribute is required in a RADIUS message containing a Tunnel-Password attribute. The default is No.  
  Server Manager property: Tunnel Password Requires Message Authenticator                                                                                                                                                                                                                       |
authfile and EAP.authfile

The authfile can be used to configure per-realm actions, but the actions in the authfile should be user data retrieval instead of authentication. For example, if a realm retrieves its user data from an LDAP directory with an LDAP Search operation to do EAP authentication, that realm must be configured in the authfile with the ProLDAP AATV and then again in the EAP.authfile with the EAP AATV.

The EAP.authfile is used to configure per-realm authentication actions. The distributed copy of this file contains a DEFAULT entry such as:

```
DEFAULT iaaaAuthenticate "default"
```

That provides the conventional authentication logic for any realm not explicitly configured to authenticate their users in a particular way, for example, PAP and Kerberos. Realms that do need some particular method for user authentication must be configured here explicitly.

The entries in these files correspond to the Local Realms page in Server Manager.

Authfile Entry Syntax

```
realm-name -flags auth-type auth-parameter

or

realm-name -flags auth-type auth-parameter
{
   extended-auth-parameters
}
```

- `realm-name` - portion of the NAI format login following the @ sign (e.g.: yourcompany.com).
- `flags` - the optional flags are used to specify additional information about this realm entry. See Protocol and Case-sensitivity Flags below.
- `auth-type` - name of the Authentication-Type, as defined in the dictionary.
- `auth-parameter` - meaning varies by Authentication-Type.
- `extended-auth-parameters` - a sequence of parameters and values which vary by Authentication-Type.

Some Authentication-Types have an extended authentication parameter block as shown in the second example above. The content varies by Authentication-Type.

Examples

```
bigearth.net   iaaaFile   flatearth
```
If users in the same realm require different authentication methods, you may be able to specify which realm entry to use by putting a flag in the authfile mapping. The flags match one of five mutually exclusive protocol identifiers that may be present in the Access-Request, plus a sixth “default” flag for users who do not explicitly match one of the other attributes. See “Configuring EAP-AKA” on page 270 for information on configuring EAP-AKA. See “Configuring EAP-SIM” on page 291 for information on configuring EAP-SIM.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Matches Access-Request Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>-PW</td>
<td>User-Password</td>
</tr>
<tr>
<td>-CHAP</td>
<td>CHAP-Password</td>
</tr>
<tr>
<td>-EAP</td>
<td>EAP-Message</td>
</tr>
<tr>
<td>-AKA</td>
<td>EAP-Message Data Store lookup for EAP-AKA</td>
</tr>
</tbody>
</table>

**Protocol Flags**
Case-sensitivity Flags

The RAD-Series Server can treat user names in a case-sensitive or a case-insensitive manner. These mutually-exclusive flags allow you to control that. The default is -BIN (case-sensitive). These flags are ignored for an Authentication-Type that uses an extended authentication parameter block and has filter-type capabilities.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Matches Access-Request Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>-SIM</td>
<td>EAP-Message Data Store lookup for EAP-SIM</td>
</tr>
<tr>
<td>-DEFAULT</td>
<td>None. Authentication type to use for all users who do not match one of the other flags.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Flag</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>-BIN</td>
<td>Username is not modified before authentication.</td>
</tr>
<tr>
<td>-CIS</td>
<td>Username is converted to uppercase before authentication. Therefore the data store needs to store the username in uppercase unless the datastore is case-insensitive.</td>
</tr>
</tbody>
</table>
Authentication Types

ProLDAP Authentication Type

The ProLDAP authentication type requires extended parameters to configure the connection to the LDAP server. The extended parameters look like this (required subset is in bold):

```
<realm_name> ProLDAP "<realm_comment>"
{
    Request-Attribute-For-Search <attribute_name>
    Filter-Type <filter_value>
    retrieve-only <value>
    Directory "<LDAP_directory_name>"
    {
        URL "<type>://<server>[:<port>]
        Administrator "<admin>"
        Password "<password>"
        SearchBase "<search_base>"
        Authenticate { Search | Bind | Auto }
        Filter <filter>
    }
    Directory "<LDAP_directory_name2>"
    {
        . . .
    }
}
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-Attribute-For-Search</td>
<td>This indicates the search attribute to use for a user lookup. The attribute must be a string-type (string, tag-str, octets). When PROLDAP is used for EAP-SIM or EAP-AKA, the Request-Attribute-For-Search attribute must be configured with a value of Real-Username. The default value, if not present, is User-Id.</td>
</tr>
<tr>
<td>Filter-Type</td>
<td>The RAD-Series Server can treat user names in a case-sensitive or a case-insensitive manner. These Filter-Type values allow you to control that.</td>
</tr>
<tr>
<td></td>
<td>• <strong>BIN</strong> - sets it to case-sensitive, username is used as is.</td>
</tr>
<tr>
<td></td>
<td>• <strong>CIS</strong> - sets it to case-insensitive, username is converted to uppercase before the LDAP lookup is done. Therefore, LDAP needs to store the username in uppercase unless LDAP is case-insensitive.</td>
</tr>
<tr>
<td></td>
<td>The default is BIN (case-sensitive). Username is not modified before authentication.</td>
</tr>
</tbody>
</table>
### Directory

**LDAP_directory_name** is the name of the directory. This does not have to be the actual directory name, just a unique identifier. The Directory definition can be repeated to define more LDAP servers that have the same content and configuration. When there is more than one, the RAD-Series Server will load balance the request across all the defined LDAP servers. There is no default value, if not present.

### URL

The URL (Universal Record Locator) defines the server, port and type of connection that should be used.

The connection *type* can be ldap (un-encrypted) or ldaps (SSL encrypted). If you configure it as ldaps then the certificates need to match the IP address or fully qualified domain name for it to work. If using ldaps (SSL), also specify the RAD-Series Server’s TLS CA certificate path and file in the “ProLDAP Connection Properties” on page 212.

The *server* can be a fully qualified domain name that maps to an IPv4 or IPv6 address. It also can be an IPv4 or IPv6 address. If it is an IP address then it should be enclosed in "[]". If it is an IPv6 address and there is a *port*, then it **must** be enclosed in "[]". The `ipv6_enabled` parameter controls whether IPv6 is enabled or disabled for RADIUS messages but it has no effect on LDAP communications. If the server is configured with an IPv6 address, or a domain name that maps to an IPv6 address, the LDAP communications will be IPv6.

The TCP *port* is optional and defaults to 389 for a *type* of ldap and to 636 for a *type* of ldaps.

There is no default value, if the URL is not present.

Here are several sample URLs (the double-quotes are optional):

- URL "ldap://srvr.ldap.com"
- URL "ldap://ipv6.ldap.com:389"
- URL "ldap://[192.168.3.1]:389"
- URL "ldap://[2003:34::42]:389"
- URL "ldaps://ipv4.ldap.com"
- URL "ldaps://ipv4.ldap.com:636"
- URL "ldaps://ipv6.ldap.com:636"
- URL "ldaps://[192.168.3.1]:636"
- URL "ldaps://[2003:34::42]:636"
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Administrator</td>
<td><em>Distinguished Name (dn)</em> of the administrative user permitted to search the LDAP directory. This ID should match the ID you set up on your directory for the RAD-Series Server. This user must have read access to all the users to be authenticated by the RAD-Series Server and their passwords. If this field is omitted, the server will perform a bind to the directory using the user credentials from the Access-Request if it is necessary to validate the user's password. There is no default value, if not present.</td>
</tr>
<tr>
<td>Password</td>
<td>Password used by the Administrator to bind to the LDAP directory server. <em>Password</em> is not required if there is no Administrator. There is no default value, if not present.</td>
</tr>
<tr>
<td>SearchBase</td>
<td>Required. Pointer into the directory where the RAD-Series Server will begin to search for users in this realm. Enter a comma-delimited list of attribute-value pairs that represent the directory levels, no spaces. There is no default value, if not present.</td>
</tr>
</tbody>
</table>
| Authenticate | Determines the mode to be used to access this LDAP server for this LDAP directory. There are three mode: **Bind**, **Search** and **Auto**. The default access mode is **Auto**.  
  - **Bind** When binding as the user for authentication is desired. No Policy-Pointers, check items, or reply items will be returned to the RAD-Series Server when Bind is specified.
  - **Search** When a LDAP search as the configured administrator is desired. The RAD-Series Server expects the user's password in the search result. The RAD-Series Server must perform an administrator search on the LDAP server when Policy-Pointers, check items, or reply items must be returned.
  - **Auto** When a LDAP search as the configured administrator (search anonymously if no configured administrator) is desired. After the search the RAD-Series Server expects the password to be returned in the search results. The RAD-Series Server binds as the user if the password is not available. Policy-Pointers, check items, and deny items will not be returned by the LDAP server if the RAD-Series Server reverts to bind. This mode can affect performance, since two LDAP operations may occur for one authentication.  
  IMPORTANT: You must use **Auto** with a Microsoft Active Directory. |
| Filter | Filter specifies which LDAP attribute to use in the lookup. The three values are **User-Id**, **UID** and **sAMAccountName**. **User-ID** is case sensitive in LDAP and **UID** is case insensitive in LDAP. **sAMAccountName** MUST be used when accessing Active Directory via its LDAP interface. The default value is **UID**. |
Example ProLDAP authfile configuration

```bash
# This realm uses an LDAP database
realm3.com PROLDAP "LDAP lookup"
{
    Request-Attribute-For-Search User-Id
    Filter-Type CIS
    Directory "Directory 1"
    {
        URL "ldap://ldap1.ispx.com:389"
        Administrator "cn=...,ou=...,ou=...,o=radius"
        Password "password"
        SearchBase "...,ou=...,o=radius"
        Authenticate Search
        Filter uid
    }
}
```

Prefixed users and authfiles

In the `clients` file, you may optionally specify a prefix for a client device. For any users connecting through this client, the RAD-Series Server will search for the user’s profile in a file called `prefix.users`. If the user’s profile is not found there the server will use the files `prefix.authfile` and `prefix.EAP.authfile` to authenticate the user. This allows you to specify different authentication methods for users in the same domain who may connect via different clients under different circumstances, for example: password authentication when connecting through a wired NAS, vs. EAP authentication when connecting through a wireless AP.

If a prefixed file does not exist or no prefix is specified then the regular non-prefixed file will be used. The “EAP.” prefixed `authfile` and any other FSM specified prefixed files are mandatory files.
clients

The clients file defines the access devices and RADIUS servers that this RAD-Series Server communicates with. The entries in this file correspond to your entries on the Server Manager Access Devices page and Proxies page. Prefix and reply_holdtime must be added manually to the device entry in the clients file.

Clients Entry Syntax

Name Secret type=Vendor:NAS Options [Optional-Fields]
or
Name:Auth-Port Secret type=Vendor:PROXY Options [Optional-Fields]
or
Name:Auth-Port:Acct-Port Secret type=Vendor:PROXY Options [Optional-Fields]

The keywords “type=”, “srcip=”, and “reply_holdtime=” are case-insensitive.

Examples

j.flatland.org f52tl type=Ascend:NAS

</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Device fully qualified domain name, IPv4 address, IPv6 address or a wildcard pattern (see “Using Wildcards for IP Addresses” on page 41). To use IPv6 addresses you must enable IPv6 in the aaa.config file. See ipv6_enabled, “General Server Properties” on page 199.</td>
</tr>
<tr>
<td>Auth-Port</td>
<td>Optional authentication relay port to use when proxying authentication requests to this RADIUS home server. This parameter overrides the port specified by the -pp option on the radiusd startup command.</td>
</tr>
<tr>
<td>Acct-Port</td>
<td>Optional accounting relay port to use when proxying accounting requests to this RADIUS home server. This parameter overrides the port specified by the -qq option on the radiusd startup command.</td>
</tr>
<tr>
<td>Secret</td>
<td>The shared secret between this device and the RAD-Series Server is a required entry. No spaces are allowed.</td>
</tr>
<tr>
<td>Vendor</td>
<td>Vendors whose attributes should be returned in reply messages. A list can be entered by combining vendors with a “+” between them, e.g.: Type=Microsoft+Interlink. Enter NONE to prune all VSAs. See vendors file for a list of defined vendors.</td>
</tr>
<tr>
<td>{NAS</td>
<td>PROXY}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Options   | Additional criteria for messages. A list can be entered by combining options with a “+” between them, e.g.: Type=Cisco:NAS+oldchap+debug. No spaces are allowed. The set of options for a NAS are:  
  • noencaps - Do not encapsulate vendor response (if the access device requires non-encapsulated A-V pairs).  
  • oldchap - For access devices that perform pre-RFC CHAP.  
  • debug - Dump packet traces for this client into the RAD-Series Server’s debug output file if the server is running at debug level 1 or greater.  
The set of options for a PROXY are:  
  • prune - Force pruning as if the response were being returned to an NAS. With this option the generic vendor prunes all vendor-specific attributes before a message is returned to the proxy server. This may be used to help prevent problems that might occur if unencapsulated vendor attributes are not correctly mapped in the vendors file.  
  • no_append - This is useful when a remote server does not return all of the A-V pairs that it received in the order they were received. If it is not set, the RAD-Series Server will append all the A-V pairs received from a remote server to the new A-V pairs sent in the response message.  
  • debug - Dump packet traces for this client into the RAD-Series Server’s debug output file if the server is running at debug level 1 or greater. |
| Optional-Field | All other optional fields can be in any order. Each one can appear at most once. The available optional fields are below. |
| V1 | Normally created by Server Manager, but it only needs to be added to a clients entry if you wish to specify a Prefix of ‘V1’ or ‘v1’. In that case specify this option followed by the Prefix option. |
| Prefix | Prefix to identify the users files and/or authfile and/or EAP.authfile to use for requests from this client. The prefix is prepended to the normal file name to get the name of the file to use. For example, a prefix of “west.” yields west.users, west.authfile and west.EAP.authfile which would be used in place of users, authfile and EAP.authfile. If one of the prefixed files does not exist then its corresponding standard non-prefixed file will be used. This option can only be configured by manually adding it to a device entry in the clients file. |
### Parameter | Description
--- | ---
Reply_holdtime | After a request has been replied to, it is held for a period of time in case a retransmission is necessary. This option specifies the number of seconds to hold on to a request after it has been replied to. It also is used to determine the time to wait for the Accounting-Start. The value should be twice the default retransmission period of the device involved. This option can only be configured by manually adding it to a device entry in the clients file.

SrcIP | This option specifies the source IP address for proxying requests to this client. The source port may additionally be specified, as an aid for home servers whose firewall allows communications with only certain IP addresses and/or ports.

If the client has both IPv4 and IPv6 addresses, this option controls whether the proxied requests are sent as IPv4 or as IPv6 requests. The srcip address may be a specific IPv4 address, a specific IPv6 address, the IPv4 ANY address [0.0.0.0], or the IPv6 ANY address [::]. If the IPv4 ANY address is specified, the operating system assigns the specific IPv4 address. Likewise for the IPv6 ANY address, the operating system assigns the specific IPv6 address.

The srcip option solves the problem where a home server has both an IPv4 and an IPv6 address but the home server’s RADIUS application is listening only on the IPv4 (or IPv6) interface, see “IPv6 Operation” on page 267.

The srcip can also address the situation where the proxy server has multiple IPv4 or multiple IPv6 interfaces and needs to specify the correct interface from which to send the request to the home server.

If IPv6 is not enabled and if the srcip address is IPv6, an appropriate log file message is generated and the srcip option is ignored.

If the DNS lookup determines that the client is IPv4 only (or IPv6 only) and the srcip value is IPv6 (or IPv4), an appropriate log file message is generated and the srcip option is ignored.
Realm files (.users) and default users file

Realm files provide local storage of user profiles. Create a separate file for each defined realm to store user profiles for authentication. All realm file names must end with the extension .users. If you create them through the Server Manager, they will be named whatever you specified when configuring the realm, followed by the extension .users.

The default “users” file is read into memory at startup/HUP and the (indexed) lookups are fast. The realm files are sequentially searched via file I/O for each authentication and changes take affect as soon as the file is updated.

User Entry Syntax

For the default users file the first line of each user entry consists of User-Name, optionally followed by configuration items and check item fields. Subsequent lines may contain an indented list of reply item A-V pairs. All reply item lines except for the last are followed by a comma:

User-Name check-items
   reply-item,
   reply-item,
   ...

Example

guest@library.org Password = "public", Simultaneous-Use = 20
   session-timeout = 3600,
   idle-timeout = 300

Note: For realm files the one difference is that the User-name is replaced with the User-Id. The realm name is omitted

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User-Name</td>
<td>In the default users file this is the user’s Network Access Identifier (NAI) format login string. In realm files this is the userid portion of user’s NAI format login string. Omit the realm name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>check-items</td>
<td>Any check or deny items to be matched by the Access-Requests before authorizing a user. See the dictionary for a list of valid attributes. Configuration attributes used for Interlink-specific functions may also appear here. See Configuration Attributes below for a list of valid attributes.</td>
</tr>
<tr>
<td>reply-items</td>
<td>Any reply items to be returned to the access device to provision the user session. Each line, except for the last, should be followed by a comma. See the dictionary for a list of valid attributes. Configuration attributes used for Interlink-specific functions may also appear here and will not be returned to the access device. See the dictionary for a list of valid configuration attributes.</td>
</tr>
</tbody>
</table>
General Configuration Attributes Used as Check Items

Configuration attributes provide user-level information for Interlink-specific functions. Only the User-Name attribute is required in a user entry. All other configuration attributes are optional.

Most of these attributes are configurable through the Server Manager Users:Add User page tabs. Any attribute that doesn’t have a corresponding field can be entered as an A-V pair on the Free tab or manually added to the user entry in the realm file.

See the dictionary file for a list of valid values for each attribute.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comment</td>
<td>Allows you to provide any necessary explanation for the entry.</td>
</tr>
<tr>
<td>Deny-Message</td>
<td>Specifies a string that would be returned to the user in the Access-Reject if any deny item for this user caused a rejection. The Deny-Message is only sent when a deny item comparison fails, not when a check item comparison fails. You may use an asterisk wildcard: Deny-Message = &quot;*&quot; This wildcard sends the message &quot;Access denied&quot; and the deny item that triggered the rejection. For example: Access denied, NAS-Port != 3160</td>
</tr>
<tr>
<td>Expiration</td>
<td>In date format, specifies when an entry expires. For example: Expiration = &quot;Dec 01 2004&quot; When the specified date has been reached, the user will receive an Access-Reject with the message, “Password has expired,” in response to all Access-Requests. See “Date Attribute Value Formats” on page 196 for a description of the acceptable date formats.</td>
</tr>
<tr>
<td>Xvalue</td>
<td>Provides a means to pass an integer value to a module on a per user basis. Usually used in Advanced Policy and custom applications.</td>
</tr>
<tr>
<td>Xstring</td>
<td>Provides a means to pass a string value to a module on a per user basis. Usually used in Advanced Policy and custom applications.</td>
</tr>
</tbody>
</table>
LAS Configuration Attributes Used as Check Items

These attributes provide information for the RAD-Series Server’s Local Authorization Service (LAS) function. To activate this feature, you must enable Session Tracking for the user’s realm. The following attribute may be added to a user entry to override the global default.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simultaneous-Use</td>
<td>The maximum number of active sessions the user may have. If Session Tracking is enabled for the user’s realm, then the global value set in Server Properties is the default value. Any user specific configuration of Simultaneous-Use will be used instead of the default value. A value of -1 removes the simultaneous session constraint for the user, whose simultaneous session limit is then bound by the RAD-Series Server’s overall licensed limit. The value 0 will deny access to the user.</td>
</tr>
</tbody>
</table>
Check and Reply Items

A user entry may include check and reply items to control access and provision service.

Check items are A-V pairs that are compared to A-V pairs in a received RADIUS Access-Request packet. There are two types of check items: regular check items and deny items. Regular check items are compared to the attribute value in the Access-Request message: the attributed must be present with the matching value, only if so is the user authorized. A deny item is similar: the attribute must either be not present in the Access-Request, or present but with a different value, only if so is the user authorized. Deny items use the operator != (not equal to) instead of = (equal to).

**Note:** The RAD-Series Server compares a check/deny item in the user profile with the first value that appears for that attribute in an Access-Request. The server will disregard any additional instances of the same attribute in the request. This limitation also applies to tagged attributes, like those used to establish VPN tunnels.

A reply item is an A-V pair that is returned in an Access-Accept, Access-Challenge, or Access-Reject message to provide instruction to the access device for provisioning the user. Some of these attributes, such as Session-Timeout, can be used to enforce some simple authorization policies.

**Note:** The RAD-Series Server handles multiple instances of a reply item in the user profile based on the clients file entry for the recipient. The server will consult the pruning rules in the dictionary to determine which instances to send based on the NAS type. See “clients” on page 229 for details.

Some attributes may be used as either check or reply items. In these instances, the attribute may appear in an Access-Request as a hint from the client for a value to assign to the attribute. With the exception of Service-Type and the tunneling attributes, the RAD-Series Server does not resolve hints, but you can use a check item to control access based on hints. For example, if you only wish to authenticate users requesting a Framed service, you could add Service-Type = Framed as a check item for those users.

Most check and reply item attributes are defined in the standard RADIUS RFC documentation and the dictionary file. They can be configured through the Server Manager User:Add User page tabs.

Date type attributes used for check/deny/reply attributes can be entered in many formats. See “Date Attribute Value Formats” on page 196 for a complete description of the rules.
**Interlink-specific Attributes**

Interlink-specific attributes that may be used as check or reply items are:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Day-Of-Week</td>
<td>An integer representing the day of the week, where 0 is Sunday and 6 is Saturday. This attribute is derived from the current system clock of the machine hosting the RAD-Series Server.</td>
</tr>
<tr>
<td>Reply-If-Ack-Message</td>
<td>Allows you to specify a message to return to the user if authentication succeeds. Similar to Reply-Message, but only sent in an Access-Accept packet. The normal pruning operation concentrates all Reply-Messages and Reply-If-Ack-Messages into as few Reply-Messages as possible.</td>
</tr>
</tbody>
</table>

**las.conf**

The `las.conf` file contains a list of configuration items for the RAD-Series Server's Local Authorization Service function. There are configuration sections for realms and LAS session items. These sections do not have to be maintained in a particular order; however, an object (a realm, for example) must be defined before it may be referenced.

Most parameters can be configured on the Server Manager’s Server Properties:Session Table Properties page. The parameters described here can be manually edited in `las.conf`.

**LAS Session Configuration**

These parameters let you override the RAD-Series Server’s default values related to session timing and session limits. Timing parameters are specified in seconds.

**Syntax**

```
attribute value
```
## Session Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
<th>Server Manager property:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Session-Table-Checkpoint-Interval</td>
<td>The interval, in seconds, between saves of the session table if there are any changes. The default value is 300 seconds (5 minutes).</td>
<td><strong>Session Table Checkpoint Interval</strong></td>
</tr>
<tr>
<td>Session-Checkpoint-File-Lifetime</td>
<td>This parameter specifies the age of the oldest session.las file that will be accepted by the RAD-Series Server at startup time. The age is relative to the startup time. The default is 28800 seconds (8 hours). By default, the server will ignore a session.las file written 8 or more hours before the server startup time. A value of zero indicates the server should accept the session.las file no matter how old.</td>
<td><strong>Session Checkpoint File Lifetime</strong></td>
</tr>
<tr>
<td>Session-Pending-Timeout</td>
<td>Time in seconds the RAD-Series Server waits for an Accounting-Start before moving a PENDING session into the UNCONFIRMED state. The default is 15 seconds.</td>
<td><strong>Session Pending Timeout</strong></td>
</tr>
<tr>
<td>Session-Unconfirmed-Timeout</td>
<td>Time in seconds the RAD-Series Server waits before removing a session in the UNCONFIRMED state. The default is 15 seconds.</td>
<td><strong>Session Unconfirmed Timeout</strong></td>
</tr>
<tr>
<td>Session-Collision-Timeout</td>
<td>Time in seconds the RAD-Series Server waits before removing a session in the COLLISION state. The default is 300 seconds (5 minutes).</td>
<td><strong>Session Collision Timeout</strong></td>
</tr>
<tr>
<td>Session-MIA-Timeout</td>
<td>Time in seconds the RAD-Series Server awaits the next Interim-Accounting message before moving an ACTIVE session into the MIA state, or before removing a session already in the MIA state. The default is 0, a special value that indicates the server will measure the time interval between received Interim-Acct messages, and use that measured value to time out subsequent Interim-Acct messages. A positive value represents a fixed time interval which the server will use to time out the next expected Interim-Acct message, rather than using a measured interval. A large positive value, e.g. 2147483647 seconds (over 68 years) will effectively cause the server to not terminate a session, or move an ACTIVE session into MIA state, due to the absence of an Interim-Accounting message.</td>
<td><strong>Session MIA Timeout</strong></td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Session-Dropped-Timeout</td>
<td>Time in seconds the RAD-Series Server waits before removing a session in the DROPPED state. The default is 300 seconds (5 minutes). Server Manager property: <strong>Session Dropped Timeout</strong></td>
<td></td>
</tr>
<tr>
<td>Session-Finished-Timeout</td>
<td>Time in seconds the LAS waits before removing a session in the FINISHED state. The default is 45 seconds. Server Manager property: <strong>Session Finished Timeout</strong></td>
<td></td>
</tr>
<tr>
<td>Session-Table-Limit</td>
<td>The maximum number of sessions that can be held in the Session Table. When this number is met, authentication requests that would normally result in a new session are ignored. This should not be confused with the session limit of your license. That limits the number of active sessions. The session table has to hold the active sessions and sessions in various other states waiting to be released. The default is 2147483647 (maximum allowed). Server Manager property: <strong>Session Table Limit</strong></td>
<td></td>
</tr>
<tr>
<td>Session-Table-Update-Interval</td>
<td>Time in seconds between updates to the status of sessions. From one to four session timer lists can be created, of increasingly longer update intervals. A given session will reside on at most one timer list. The update interval for the first timer list must be from 1 to 10 seconds, with a default of 5 seconds. Each subsequent timer interval, if any, must be greater than its predecessor. The longest interval cannot exceed 86400 seconds (24 hours). Note: the value of the first timer determines the granularity (precision) of the session management timers. The default is one timer list which is updated every 5 seconds. Server Manager property: <strong>Session Table Update Interval</strong></td>
<td></td>
</tr>
<tr>
<td>Simultaneous-Use</td>
<td>The maximum number of active sessions users may have, unless a user-specific value is configured that overrides this number. The default value is 1. The value -1 removes the simultaneous session constraint for all user and the total number of simultaneous sessions is then bound by the RAD-Series Server's overall licensed limit. The value 0 prevents access to any user that does not have a specific value configured. Server Manager property: <strong>Simultaneous Use</strong></td>
<td></td>
</tr>
</tbody>
</table>
### Attribute | Description
--- | ---
Simultaneous-Use-States | This parameter defines which session states count towards a user’s Simultaneous-Use limit. The default value is “Pending-Active-Unconfirmed-Expired-MIA”, which means that a user session in state PENDING, ACTIVE, UNCONFIRMED, EXPIRED, or MIA will count against the user’s Simultaneous-Use limit. These represent states that are ACTIVE or could become ACTIVE. The other supported value is “Pending-Active”, which means that a user session in state PENDING or ACTIVE will count against the user’s Simultaneous-Use limit; this is compatible with previous versions of the RAD-Series Server.
Server Manager property: **Simultaneous-Use States**

Minimum-Interim-Accounting-Timeout | This parameter sets a floor for the RAD-Series Server’s timeout for the next expected Interim-Acct request message, even if the server’s measured value is less than this value. The default is 60 seconds.
Server Manager property: **Minimum Interim Accounting Timeout**

Interim-Accounting-Grace-Period | Time in seconds the RAD-Series Server will wait for an Accounting message (Interim or Stop) before removing a session in the MIA state. The default is 15 seconds.
Server Manager property: **Interim Accounting Grace Period**

Max-Number-Of-Acct-Records-Per-Second | The RAD-Series Server will internally generate an Acct-Stop record for a session which is terminating without benefit of having received an Acct-Stop request from the NAS, such as sessions which terminate in COLLISION or MIA state. The parameter limits the server’s rate of generating such accounting records, to avoid overtaxing of resources. For example, a server with thousands of sessions might be suddenly tasked with writing many accounting records upon receiving an Accounting-Off request from a NAS; this parameter can be used to distribute that workload over several seconds. The default is 100 server-generated accounting records per second.
Server Manager property: **Maximum Number Of Server-Generated Acct Records per second**

Session-Id-Prefix | The Session-Id-Prefix is an alphanumeric character string, 2 to 8 characters in length. The RAD-Series Server generates a session-id which begins with this character string. The default value is “AAA”. The Session-Id Prefix helps distinguish the Class attribute which contains the RAD-Series Server’s session-id from other Class attributes that may be present in a RADIUS message.
Server Manager property: **Session-Id Prefix**
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accounting-OnOff-Support</td>
<td>When this option is set to Yes, the RAD-Series Server will clear all sessions for a NAS who sends an Accounting Request message with Acct-Status-Type=Accounting-On or Acct-Status-Type=Accounting-Off. When set to No, the Accounting Request will be acknowledged, but the server will take no action regarding the NAS's sessions. The default is Yes.</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: Accounting-On / Accounting-Off Support</td>
</tr>
<tr>
<td>Extra-Logging</td>
<td>If set to Yes, the RAD-Series Server will log additional information regarding session events. For example, the RAD-Series Server will always log notifications of unexpected session transitions, such as transitions into COLLISION or UNCONFIRMED states. If this parameter is set to Yes, the server will also log normal transitions, such as from ACTIVE to FINISHED state. This parameter is intended for those wanting closer monitoring of session events.</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: Extra Logging</td>
</tr>
<tr>
<td>Session-Collision-Checking</td>
<td>When this option is set to Yes, the LAS will check if a newly-received authentication request comes from the same NAS (as identified by the NAS-Identifier or NAS-IP-Address or NAS-IPv6-Address attribute) and port (as identified by the NAS-Port attribute) as an existing active session. If so, the existing session is put into an non-active state and the newly-received authentication request becomes the new sole owner of that NAS/Port. When set to No, the RAD-Series Server will not check for concurrent usage of the same NAS and port. This parameter is intended for use by NASes which distinguish their ports and allow only one active session on a given port, to recognize and clear out previous sessions on the given NAS/Port for which the LAS did not receive a termination notice (normally an Accounting-Stop message). The default is Yes.</td>
</tr>
<tr>
<td></td>
<td>Server Manager property: Session Collision Checking</td>
</tr>
</tbody>
</table>
Generic Tokenpool Configuration

This section describes the configuration and use of generic token pools. Token pools are not configurable via the Server Manager and must be manually edited, however the Server Manager will preserve any Tokenpool configurations it encounters.

Generic token pools can be used to limit or monitor access to resources. The RAD-Series Server tracks the number of tokens currently in use, as well as the high-water mark of tokens in use, for each token pool. The server tokenpool statistics are reported by the radcheck utility, and by the Server Manager’s Administration>Status button.

During user authentication, a token can be requested for a user in one of two ways:

- A user can be explicitly configured with one or more `Token=<poolname>` reply-items, where `Token` is an internal dictionary attribute and `<poolname>` is the name of a token pool matching a configured `Tokenpool`, or
- A policy step can evaluate the user’s Access-Request and determine if one or more token requests should be made for this request, and if so appending `Token=<poolname>` attribute(s) to the request.

If a token is requested for a session-tracked session from a non-empty token pool, a token is allocated from the pool and assigned for the duration of the session. When the session ends, the token is returned to the pool for re-use by another session. The accounting logfile will contain attributes reflecting the tokens used by the session. A session may request tokens from multiple pools. Configuring a large number of tokens allows resource usage to be monitored without being limited.

If a token is requested for a session that isn’t tracked, or if the specified token pool is empty, the user’s access request is rejected.

Syntax

```
Tokenpool  pool-name  number-of-tokens
```

Tokenpool Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pool-name</code></td>
<td>The name of a defined token pool</td>
</tr>
<tr>
<td><code>number-of-tokens</code></td>
<td>The number of tokens in that pool</td>
</tr>
</tbody>
</table>
LAS Realm Configuration

This section lists session-tracked realms by name. Turning on Session Tracking through the Server Manager automatically adds a realm entry to las.conf.

**Note:** If you make a realm entry by editing las.conf directly and then disable Session Tracking through the Server Manager, the entry will be deleted.

**Syntax**

Realm realm-name
End-Realm

**Realm Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Realm</td>
<td>Required, defines the name of a realm whose sessions will be tracked.</td>
</tr>
<tr>
<td>End-Realm</td>
<td>Optional, defines the end of the Realm block</td>
</tr>
</tbody>
</table>

**Logging LAS Realms**

The default RAD-Series Server behavior is to log accounting messages locally, whether the server processes Access-Request messages locally or sends them to a remote server. If a realm entry exists in las.conf, the server will NOT send accounting messages to the server that processed the authentication for the corresponding user.
vendors

The `vendors` file contains a list of entries defining vendors whose attributes are recognized by the RAD-Series Server. Each vendor entry contains a vendor name and vendor number. The vendor numbers are SMI Network Management Private Enterprise Code numbers (integers), as managed by IANA.

Entries may optionally contain an interim way of mapping external (with respect to the RADIUS server) attribute numbers to internal vendor-specific attributes. This optional mapping is used in RADIUS requests and responses. This is used primarily to support very old NAS implementations. It should not be necessary when adding new vendors.

Version Tracking

You can track different versions of the vendors file by changing the following line in the file:

```%
VENDORSID Version-String
```

*Version-String* is the version identifier. If you need to modify the vendors file, it is recommended that you modify the version string by adding to the end of the current string. This string will appear in `radcheck` output.

Vendor Entry Syntax

```
Attribute-String Value-String Vendor-Code Vendor-Name
{
   Standard-Value Vendor-Specific-Value
   . . .
}
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attribute-String</td>
<td>An optional string that defaults to ATTRIBUTE when not specified. When adding</td>
</tr>
<tr>
<td></td>
<td>vendor-specific attributes to the dictionary file, enter the string that will</td>
</tr>
<tr>
<td></td>
<td>be used to identify the attributes. You must also specify Value-String.</td>
</tr>
<tr>
<td>Value-String</td>
<td>An optional string that defaults to VALUE when not specified. When adding</td>
</tr>
<tr>
<td></td>
<td>vendor-specific values to the dictionary file, enter the string that will</td>
</tr>
<tr>
<td></td>
<td>be used to identify the values.</td>
</tr>
<tr>
<td>Vendor-Code</td>
<td>The private enterprise number assigned by IANA.</td>
</tr>
<tr>
<td>Vendor-Name</td>
<td>Vendor identifier that will appear in the clients file as a type=vendor:nas</td>
</tr>
<tr>
<td></td>
<td>entry or in the dictionary and .users files in vendor-specific attributes.</td>
</tr>
</tbody>
</table>
Standard-Value and Vendor-Specific-Value are used to map attributes from the common attribute space defined in the RADIUS RFC to internal non-conflicting vendor-specific attributes. They address backward compatibility issues for very old NASes. You should not have to use these parameters for new VSA definitions.

**Example**

<table>
<thead>
<tr>
<th>Merit.Attribute</th>
<th>Merit.Value</th>
<th>61</th>
<th>Merit</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>144</td>
<td>144</td>
<td></td>
</tr>
<tr>
<td></td>
<td>145</td>
<td>145</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>...</td>
</tr>
</tbody>
</table>
**dictionary**

The dictionary file contains a list of dictionary translations that the RAD-Series Server uses to parse incoming requests and to generate outgoing responses. It includes definitions of all attributes and their permitted values.

**Version Tracking**

You can track different versions of the dictionary by changing the following line in the file:

```plaintext
%DICTID Version-String
```

*Version-String* is the version information. If you need to modify the dictionary, it is recommended that you modify the version string by adding to the end of the current string. This string will appear in *radcheck* output.

**Attribute Entry Syntax**

```plaintext
{ATTRIBUTE|Attribute-String} Attribute-name Integer-encoding Type
(pruning) # comment
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attribute-String</td>
<td>Vendor-specific attribute identifier defined in the vendors file. If no Attribute-String is defined, use ATTRIBUTE.</td>
</tr>
<tr>
<td>Attribute-name</td>
<td>Unique name of an attribute.</td>
</tr>
<tr>
<td>Integer-Encoding</td>
<td>Actual attribute number code.</td>
</tr>
<tr>
<td>Type</td>
<td>The attribute type. May be:</td>
</tr>
<tr>
<td></td>
<td>• octet: 8-bit unsigned integer value</td>
</tr>
<tr>
<td></td>
<td>• short: 16-bit unsigned integer value</td>
</tr>
<tr>
<td></td>
<td>• integer: 32-bit value in big endian order (high byte first)</td>
</tr>
<tr>
<td></td>
<td>• date: 32-bit value in big endian order (seconds since 00:00:00 GMT, Jan. 1, 1970)</td>
</tr>
<tr>
<td></td>
<td>• octets: 0-253 undistinguished octets</td>
</tr>
<tr>
<td></td>
<td>• abinary: 0-253 Ascend binary filter octets</td>
</tr>
<tr>
<td></td>
<td>• string: 0-253 octets</td>
</tr>
<tr>
<td></td>
<td>• vendor: 0-253 octets with octets 0-3 representing the IANA number</td>
</tr>
<tr>
<td></td>
<td>• ipaddr: IPv4 address: 4 octets in network byte order</td>
</tr>
<tr>
<td></td>
<td>• ipv6addr: IPv6 address: 16 octets, in network byte order</td>
</tr>
<tr>
<td></td>
<td>• ipv6prefix: 2 octets of prefix length followed by 0-16 octets of IPv6 prefix, in network byte order</td>
</tr>
<tr>
<td></td>
<td>• interfaceid: Interface id: 8 octets in network byte order</td>
</tr>
<tr>
<td></td>
<td>• tag-int: single octet followed by three octets of integer value (used for tunneling attribute)</td>
</tr>
<tr>
<td></td>
<td>• tag-str: single octet followed by 0-252 octets (used for tunneling attribute)</td>
</tr>
</tbody>
</table>
**Pruning Expressions and Flags**

Pruning is a feature that allows the RAD-Series Server to remove A-V pairs from an Access-Accept, Access-Reject, or Access-Challenge message before sending the message to a client (generally a NAS) that has been configured for pruning in the clients file (Type=NAS or Type=proxy+prune). The pruning is defined by optional pruning expressions in the dictionary attribute entries.

Pruning is expressed in an attribute entry as follows:

\[(\text{ack, nak, chall, NOLOG, ENCAPS|NOENCAPS, CONFIG, INTERNAL, ENCRYPT_SALT, MASK_VALUE})\]

If the \text{ack}, \text{nak}, or \text{chall} value is omitted, but the comma is present for that expression, the default value of 0 is used. If no pruning expressions are specified, all defaults are used.

\text{ack, nak, chall}: How many instances of the dictionary attribute to add to an Access-Accept, Access-Reject, or Access-Challenge, respectively. May be one of the following values:
- 0—No attributes of this kind (default value)
- 1—One attribute of this kind (last occurrence on the reply list)
- *—any number of attributes of this kind

\text{NOLOG}: Do not add the attribute to RAD-Series Server log file or session logs.

\text{ENCAPS}: Encapsulate the value in the vendor-specific attribute, regardless of the vendor (default value).

\text{NOENCAPS}: Do not encapsulate the value within the vendor-specific attribute. \text{ENCAPS} and \text{NOENCAPS} keywords are mutually exclusive. If you specify both, only the last one will apply.

\text{CONFIG}: This option means the attribute is only for the internal use only. The \text{CONFIG} pruning option may not be combined with any other pruning option.

\text{INTERNAL}: This option means the attribute is for internal use only and the attribute will not be sent or received.

\text{ENCRYPT_SALT}: The attribute's value is encrypted using the generic salt encryption algorithm.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pruning</td>
<td>Optional pruning expression that controls:</td>
</tr>
<tr>
<td></td>
<td>• Sending A-V-pair to NAS</td>
</tr>
<tr>
<td></td>
<td>• Logging the attribute</td>
</tr>
<tr>
<td></td>
<td>• Encapsulation</td>
</tr>
<tr>
<td></td>
<td>• Internal attribute identification</td>
</tr>
<tr>
<td>Comment</td>
<td>Optional comment about the entry.</td>
</tr>
</tbody>
</table>
when transmitted in RADIUS messages.

**MASK_VALUE:** The attribute's value is masked when logged.

---

**Note:** Always specify pruning expressions for vendor-specific attributes or they will not be returned to the client in any replies.

---

**Example**

```
ATTRIBUTE Framed-Protocol 7 integer (1, 0, 0)
ATTRIBUTE Password 1033 string (CONFIG,MASK_VALUE)
ATTRIBUTE Tunnel-Password 69 tag-str (*, 0, 0, ENCRYPT_SALT)
Merit.ATTRIBUTE User-Realm 223 string (*, 0, 0, ENCAPS,INTERNAL)
Interlink.Attr Address-Pool 1 string (0, 0, 0, INTERNAL)
```

---

**Generic Salt Encryption**

The values of some attributes are always transmitted in an encrypted form, using the generic salt encryption algorithm. The `Tunnel-Password` attribute ([RFC2548](https://www.ietf.org/rfc/rfc2548.txt)) and the `MS-MPPE-Recv-Key` and `MS-MPPE-Send-Key` attributes ([RFC2868](https://www.ietf.org/rfc/rfc2868.txt)) are examples of such attributes. The generic salt encryption algorithm is defined in these RFCs. Some vendor specific attributes, e.g. `Unisphere-Med-Ip-Address`, are also transmitted in encrypted form, using the same generic salt encryption algorithm.

The RAD-Series server recognizes an attribute as needing generic salt encryption/decryption if the attribute is configured with the `ENCRIPT_SALT` flag in the dictionary. A second flag, `MASK_VALUE`, can be additionally configured, which causes the RAD-Series server to mask the value of sensitive attributes when displayed in logfiles.

The RAD-Series Server supports the salt-encryption of all attribute types, i.e. abinary, date, integer, interfaceid, ipaddr, ipv6addr, ipv6prefix, octet, octets, short, string, tag-int, and tag-str.

The `radpwtst` utility supports the sending and receiving of salt-encrypted attributes. The attributes to be sent should be specified unencrypted and `radpwtst` will encrypt them before sending e.g. “`radpwtst -:Tunnel-Password=:1:mypassword ...`”

---

**Value Entry Syntax**

Valid values for integer-type attributes may be defined in the dictionary file. Define each value on a separate line.

```
{Value-String|VALUE} Attribute-Name Value-Name Integer-Encoding
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value-String</td>
<td>Vendor-specific value identifier string defined in the vendors file. If no</td>
</tr>
<tr>
<td></td>
<td>value-string is defined, use VALUE.</td>
</tr>
<tr>
<td>Attribute-Name</td>
<td>The name of the attribute associated with this value.</td>
</tr>
<tr>
<td>Value-Name</td>
<td>The name/descriptor of the value.</td>
</tr>
<tr>
<td>Integer-Encoding</td>
<td>The actual value used in the A-V pair data format.</td>
</tr>
</tbody>
</table>

**Example**

<table>
<thead>
<tr>
<th>VALUE</th>
<th>Framed-Protocol</th>
<th>PPP</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE</td>
<td>Framed-Protocol</td>
<td>SLIP</td>
<td>2</td>
</tr>
<tr>
<td>Interlink.VALUE</td>
<td>EAP-Type</td>
<td>TLS</td>
<td>13</td>
</tr>
<tr>
<td>Interlink.VALUE</td>
<td>EAP-Type</td>
<td>PEAP</td>
<td>25</td>
</tr>
</tbody>
</table>

**log.config**

The `log.config` file specifies how accounting logs are generated in the RAD-Series Server. It allows you to configure multiple logging streams, which can be used with sophisticated Finite State Machine (FSM) tables. For most applications, configuration of the default stream will suffice.

For any stream, you can configure log file format, location, name, and how often streams are switched between files. There are six possible entry types that control special logging features and options for a stream.

**Default Entry**

The `default` entry specifies the name of the stream to use as the default and follows the syntax:

```
default stream-name
```

**Default Path Entry**

The `default-path` entry specifies the default path for session log files. The `default-path` does not apply to the `*default*` stream. The `default-path` follows the syntax:

```
default-path pathname
```

**Default-dateformat Entry**

The `default-dateformat` entry specifies the default format for printing date type attributes in the accounting log files and follows the syntax:

```
default-dateformat date-format
```

The `date-format` is a strftime format string that defines how the date type attributes should be displayed. The conversion specifications of strftime can be found by doing a `man strftime`. An example strftime format is `"%Y-%m-%d %H:%M:%S"` which would yield a date in this format: ‘2011-01-30 16:12:59’. If this optional entry is not present then all the date type attributes in the accounting logfiles will be displayed in the original format as follows:

- LOG_V2_0 (= default Merit) accounting displays its date value as yyyy-mm-dd, e.g. “2010-02-24” in local time zone.
- LOG_ACCT (=Livingston accounting) displays a date value “mmm d yyyy”, e.g. “Feb 24 2010”, in local time zone.

**Default-dateformat-timezone Entry**

The `default-dateformat-timezone` entry specifies the default time zone used for printing date type attributes in the accounting log files and follows the syntax:
default-dateformat-timezone { gmt | utc | local }

The `default-dateformat-timezone` parameter controls whether the date type attributes displayed with the `default-dateformat` string are presented as UTC or in the local time zone. It does not cause the time zone mnemonic to be displayed. If you want the time zone displayed, you can use the `%Z` in `default-dateformat` or `dateformat` if it works on your system or just add the correct characters to `default-dateformat` or `dateformat`, like this: `'%Y-%m-%d %H:%M:%S EDT'`.

The default, if `default-dateformat-timezone` is not present, is the local time zone. The `default-dateformat-timezone` parameter applies only to the configured `default-dateformat` and the `dateformat` parameter, defined below. If neither of these is configured, then `default-dateformat-timezone` is ignored.

The values 'gmt' and 'utc' are synonyms.

**Nodefault Entry**

The one-keyword `nodefault` entry turns off the defaulting feature. When this entry is used, the default stream name must be identified by the `STRVALUE=keyword` in the finite state machine. Don't use this unless you have some idea of how to manipulate the finite state machine.

**Stream Entry**

```
stream name { 
  aatv        AATV_NAME
    aatv-value    integer
    filename      string
    buffer        integer
    chmod         octal-value
    close         {on|off}
    dateformat    string
    dateformat-timezone  {gmt|utc|local}
    debug         integer
    dont          attribute attribute . . .
    gmt|local
    join          joined_stream
    header        {none|Type|full}
    on-endfile    shell-command
    path          pathname
    update        seconds
    wrap          integer

} 
end
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stream</td>
<td>The name following this keyword identifies the stream.</td>
</tr>
</tbody>
</table>
| aatv      | This required parameter for any stream is the AATV to use for logging the stream.  
  - LOG_ACCT (Livingston/Lucent/RABU style call detail format)  
  - LOG_ALL (logs all streams defined in log.config)  
  - LOG_BRIEF (simple session format)  
  - LOG_BY_ATTRIBUTE  
  - LOG_BY_NAS  
  - LOG_BY_REALM  
  - LOG_V2_0 (default Merit style logging) |
| aatv-value| The Xinteger value to pass to the AATV. The default is 7. |
| buffer    | The number of records to buffer before flushing the buffers to disk. The default is 1. |
| chmod     | The value is an octal UNIX permission value; must have a leading 0. The default is 0640. |
| close     | The value of on causes the RAD-Series Server to open/close file for each flush. The value of off causes the server to not open/close file for each flush. The default is off. |
| dateformat| This strftime format string works just like default-dateformat, defined above, except that it applies to this logging stream only. The default, if not present, is to use the default-dateformat string if it is present, else to use the old format of 'yyyy-mm-dd' (LOG_V2_0) or 'mmm dd yyyy' (LOG_ACCT) |
| dateformat-timezone | This controls whether the date attributes displayed with the dateformat string are presented as UTC or in the local time zone. It works just like default-dateformat-timezone, defined above, except that it applies to this logging stream only.  
  The default, if not present, is default-dateformat-timezone if it is present, else it is the local time zone. The dateformat-timezone parameter applies only to the configured dateformat parameter. If dateformat is not configured, then dateformat-timezone is ignored. |
<p>| debug     | The value specifies the logging debug level for accounting messages. If the RAD-Series Server is running at least at debug level 1, then if the logging debug level is &gt; the current debug level, raise the debug level to the logging debug level while we are logging the accounting message. Valid values are 0 to 4. The default is 0. |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dont</td>
<td>The value is a list of one or more RADIUS accounting attributes that should not be included in the session log file. The default is none.</td>
</tr>
<tr>
<td>filename</td>
<td>The file name format to use for this stream. The default is “session.%Y-%m-%d.log”.</td>
</tr>
<tr>
<td>utc</td>
<td>gmt</td>
</tr>
<tr>
<td>header</td>
<td>Specifies the amount of header information to be written to the session logfile. <strong>none</strong> adds no header lines, <strong>type</strong> adds just the first 3 lines of header information and <strong>full</strong> adds all the header lines. The default is full.</td>
</tr>
<tr>
<td>join</td>
<td>Specifies the stream name of another stream to join to this stream. The joined stream must already be defined. This will allow logging the same accounting message to multiple streams (i.e.: produce multiple outputs.) There is no default.</td>
</tr>
<tr>
<td>on-endfile</td>
<td>This specifies a shell command to run when the session log file is rolled to a new filename. Do not enclose the command in quotes. If the command has a “!” in it, then, before executing the command, the “!” will be replaced by the file name in use before the rollover occurred. A common usage is to compress the accounting log at rollover time via on-endfile gzip -9 ! There is no default.</td>
</tr>
<tr>
<td>path</td>
<td>The value specifies the path to be used for session log files. Do not enclose the path in quotes. The default is the -a option used when starting radiused or /var/opt/aaa/acct if no -a option was used.</td>
</tr>
<tr>
<td>update</td>
<td>The value is the interval in seconds between flushes of the buffer to the session logfile. The default is 900 seconds (15 minutes).</td>
</tr>
<tr>
<td>wrap</td>
<td>The number of A-V pairs to put on a line before wrapping to a new line. The default is 3.</td>
</tr>
<tr>
<td>end</td>
<td>This required parameter for any stream is the keyword that tells the RAD-Series Server to stop reading the configuration file, allowing subsequent text to be ignored.</td>
</tr>
</tbody>
</table>

**Logging Multiple Streams**

To log multiple streams, define a stream named **default** with the **aatv** subcommand set to **LOG_ALL**. All other streams defined in **log.config** will also generate accounting logs.
stream *default* {
  aatv        log_all
}

stream livingston {
  aatv        log_acct
  buffer      1
  close       on
  filename    livingston.%Y%m%d.log
}

stream new {
  aatv        log_v2_0
  aatv-value  7
  buffer      1
  close       on
  filename    merit.%Y%m%d.log
}

end
iaaaAgent.conf

The iaaaAgent.conf file contains one parameter, agentxPingInterval, which is set to 30 seconds by default. This setting specifies how often the RAD-Series Server’s SNMP subagent will check to see if a master agent is active. If one is detected and the subagent has not already registered with the master agent, the subagent will register with the master agent and begin processing SNMP requests.

Finite State Machine (FSM)

The main component of the RAD-Series Server's software engine is the Finite State Machine and a few associated routines. At RAD-Series Server startup the finite state machine loads state table instructions from an .fsm file. It will load the radius.fsm file, unless it is missing or another .fsm file is specified by the radiusd -f option.

The .fsm file defines a state table that includes the states, events, and actions that determine how a request is processed.

Version Tracking

You can track different versions of state tables by adding the following line to the file:

%FSMID Version-String

• The % must be in the first column.
• Version-String is the version information. This string will appear in radcheck output.

States

Each state defined in a finite state table starts with a line containing just the name of the state, followed by a colon character. There can be up to 1,024 states defined. Each subsequent line is an event handler with three required and two optional fields. The fields on the line can be separated by spaces and/or tabs:

State-name:

Event-1 Action-1 Next-state-1 intattr=value stringattr=value

... ...

Event-n Action-n Next-state-n intattr=value stringattr=value

• Every State-name must start in column 1.
• Every Event-n must not start in column 1.
• Every State-name referenced in an event handler must be defined only once in the state table.
• Every State-name, except for the End, must have at least one associated event handler.
• Every State-name, except for Start, must be referenced by at least one event handler in another state as its next state.

The parameters for any event are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>State-name</td>
<td>An arbitrary string which represents a state in the FSM. It may be composed of any printable ASCII character except space, new line, carriage return, tab, and colon (:) characters.</td>
</tr>
<tr>
<td>Event</td>
<td>Three-tuple with each part separated by a period in the form: Last-state.Last-action.Event-name</td>
</tr>
<tr>
<td>Action</td>
<td>Name of the module to call in this event. The called module will return a value that will be used as the next event. For reference, you may refer to a list of “Predefined Actions” in the SDK documentation. Typically, the RAD-Series Server invokes iaaaRealm upon receipt of an authentication request. iaaaRealm in turn invokes the proper authentication module (PROLDAP, ORACLE, etc.), depending on the configuration of the request in question. This process is specific to the server’s default state table.</td>
</tr>
<tr>
<td>Next-state</td>
<td>Name of next state in the AAA transaction. The current State-name, Action, and the value returned from the Action (an event) determine which event listed under Next-state should be processed next.</td>
</tr>
</tbody>
</table>
Events

After an action completes its task, it returns an event code name to the FSM. The previous state and action and the event code name determine the current event, which in turn determines the next action of the FSM. The event code names returned by the standard AAA actions are predefined, but you can create your own names by modifying the .fsm file.

Predefined Event Names

An action may return one of the following predefined events:

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACC_CHAL</td>
<td>The incoming proxy reply is an Access-Challenge or an Access-Challenge should be sent in response to an Access-Request.</td>
</tr>
<tr>
<td>ACCT</td>
<td>The incoming request is an Accounting-Request.</td>
</tr>
<tr>
<td>ACCT_ALIVE</td>
<td>The incoming Accounting-Request is an interim accounting message.</td>
</tr>
<tr>
<td>ACCT_OFF</td>
<td>Received accounting message has a Status-Type of Accounting-Off.</td>
</tr>
<tr>
<td>ACCT_ON</td>
<td>Received accounting message has a Status-Type of Accounting-On.</td>
</tr>
<tr>
<td>ACCT_START</td>
<td>Received accounting message has a Status-Type of Start.</td>
</tr>
<tr>
<td>ACCT_STOP</td>
<td>Received accounting message has a Status-Type of Stop.</td>
</tr>
<tr>
<td>ACCT_TUNNEL_LINK_REJECT</td>
<td>The incoming Accounting-Request is a message that the user has been denied access to an established tunnel.</td>
</tr>
<tr>
<td>Event</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ACCT_TUNNEL_LINK_START</td>
<td>The incoming Accounting-Request is a message to start a session through an established tunnel.</td>
</tr>
<tr>
<td>ACCT_TUNNEL_LINK_STOP</td>
<td>The incoming Accounting-Request is a message to end a session through an established tunnel.</td>
</tr>
<tr>
<td>ACCT_TUNNEL_REJECT</td>
<td>The incoming Accounting-Request indicates that a requested tunnel could not be established.</td>
</tr>
<tr>
<td>ACCT_TUNNEL_START</td>
<td>The incoming Accounting-Request is a message to establish a tunnel.</td>
</tr>
<tr>
<td>ACCT_TUNNEL_STOP</td>
<td>The incoming Accounting-Request is a message to eliminate a tunnel.</td>
</tr>
<tr>
<td>ACK</td>
<td>Acknowledgment of the previous action.</td>
</tr>
<tr>
<td>AUTHEN</td>
<td>The incoming request is an Access-Request.</td>
</tr>
<tr>
<td>AUTHENTICATE</td>
<td>The incoming request is a proxied Access-Request.</td>
</tr>
<tr>
<td>AUTH_ONLY</td>
<td>Received Access-Request has a Service-Type of Authenticate-Only.</td>
</tr>
<tr>
<td>CHAL_WAIT</td>
<td>The incoming proxy reply is an Access-Challenge or an Access-Challenge should be sent in response to an Access-Request.</td>
</tr>
<tr>
<td>CONTINUE</td>
<td>The incoming Access-Request is a continuation of an in-progress EAP conversation. Generally, you should allow the RAD-Series Server to handle these events without modification. This event is not pre-defined, it must be defined in the FSM file.</td>
</tr>
<tr>
<td>DROP</td>
<td>The request should be dropped, no further processing will occur. This event is not pre-defined, it must be defined in the FSM file with a value that matches the value of DROP for the Interlink-Reply-Status attribute in the dictionary.</td>
</tr>
<tr>
<td>DUP</td>
<td>The incoming Access-Request is a duplicate. Generally, you should allow the RAD-Series Server to handle these events without modification.</td>
</tr>
<tr>
<td>ERROR</td>
<td>The previous action generated an error. Generally, you should allow the RAD-Series Server to handle these events without modification.</td>
</tr>
<tr>
<td>LAS_ACCT</td>
<td>The incoming request is a LAS proxied Accounting-Request.</td>
</tr>
<tr>
<td>NAK</td>
<td>Negative acknowledgment of the previous action.</td>
</tr>
</tbody>
</table>
Creating New Event Names

To create custom event names, add to the .fsm file:

```
%event name value
```

- The `%` must be in column 1.
- `name` can be any alphanumeric string and may include underscores (_).
- `value` is an optional integer value for the event which allows your custom plugin to use a specific value for an event.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_SUCH_REALM</td>
<td>This value may be returned by the iaaaRealm action when a user’s realm cannot be found in the file that iaaaRealm checked (authfile by default).</td>
</tr>
<tr>
<td>PROXY_EGRESS</td>
<td>This value may be returned by the RAD2RAD AATV (RADIUS proxy) module to indicate that a request is about to be forwarded. In the default FSM this invokes the proxy post-processing policy. This event is not pre-defined, it must be defined in the FSM file.</td>
</tr>
<tr>
<td>PW_EXPIRED</td>
<td>This value may be returned by the iaaaAuthenticate AATV module if the user profile includes an out-of-date value for the Expiration configuration attribute.</td>
</tr>
<tr>
<td>RETRIEVE_DEFAULT</td>
<td>This value is returned by the iaaaRealm or iaaaUsers action when the search for a user’s profile returns the DEFAULT entry.</td>
</tr>
<tr>
<td>RETRIEVE_ERROR</td>
<td>This value may be returned by the user profile retrieval (iaaaRealm, iaaaUsers) when a user’s profile cannot be found. Also returned when the “DEFAULT” entry is “found”.</td>
</tr>
<tr>
<td>RETRIEVE_SUCCESS</td>
<td>This value may be returned by the iaaaRealm or iaaaUsers action when the search for a user’s profile is successful.</td>
</tr>
<tr>
<td>RETRY_LIMIT</td>
<td>The number of received duplicate requests has exceeded the retry limit.</td>
</tr>
<tr>
<td>SEND</td>
<td>Typically used after a post-processing policy to cause the request to be forwarded or the reply to be sent. This event is not pre-defined, it must be defined in the FSM file.</td>
</tr>
<tr>
<td>TIMEOUT</td>
<td>The request has timed out due to inactivity.</td>
</tr>
<tr>
<td>TIMER</td>
<td>The timer value has expired.</td>
</tr>
<tr>
<td>WAIT</td>
<td>The previous action generated a pending event. Generally, you should allow the RAD-Series Server to handle these events without modification.</td>
</tr>
</tbody>
</table>
• You may define a new event anywhere in the .fsm file, but it must be defined before it is referenced.

### Actions

The actions in the state table correspond to the RAD-Series Server's AATV actions. These actions perform discrete functions, such as initiating an authentication request, replying to an authentication request, or logging an accounting record. For any action used in the .fsm file, there must be a corresponding AATV of the same name.

The following table lists some of the available actions.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCT</td>
<td>Writes Livingston call detail records</td>
</tr>
<tr>
<td>ACCT_SWITCH</td>
<td>Direct FSM to next state based on reason code of the Accounting-Request</td>
</tr>
<tr>
<td>ACC_CHAL</td>
<td>Returns an ACC_CHAL event</td>
</tr>
<tr>
<td>ACK</td>
<td>Signifies success</td>
</tr>
<tr>
<td>CHK_DENY</td>
<td>Verifies check items in user profile.</td>
</tr>
<tr>
<td>CONTINUE</td>
<td>Resume processing of an in-progress EAP conversation</td>
</tr>
<tr>
<td>iaaaAuthenticate</td>
<td>Performs authentication (following profile retrieval)</td>
</tr>
<tr>
<td>iaaaFile</td>
<td>Attempts to retrieve a user profiles from realm users files</td>
</tr>
<tr>
<td>iaaaRealm</td>
<td>Attempts a realm-based dispatch using the specified authfile to locate where a user profile is stored or the authentication type for the realm extracted from a user request</td>
</tr>
<tr>
<td>iaaaUsers</td>
<td>Retrieves user profiles from the default users file</td>
</tr>
<tr>
<td>LAS</td>
<td>Evaluates realm-based authorization for L.A.S.</td>
</tr>
<tr>
<td>LAS_ACCT</td>
<td>Initial action to handle an Accounting-Request for L.A.S.</td>
</tr>
<tr>
<td>localFile</td>
<td>Retrieves user profiles from realm files based on the Request-Attribute-For-Search option which defaults to User-ID</td>
</tr>
<tr>
<td>LOG</td>
<td>Writes accounting logs as defined in log.config</td>
</tr>
<tr>
<td>NAK</td>
<td>Returns an NAK event</td>
</tr>
<tr>
<td>NULL</td>
<td>No action placeholder.</td>
</tr>
<tr>
<td>PASSWD</td>
<td>Verifies password against Unix password system</td>
</tr>
<tr>
<td>Action</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>POLICY</td>
<td>Evaluates advanced policies</td>
</tr>
<tr>
<td>POSTLAS</td>
<td>Saves, in the session entry, the IP address allocated by the DHCP-Relay, if one was assigned.</td>
</tr>
<tr>
<td>PROLDAP</td>
<td>Retrieves user profile from an LDAP server</td>
</tr>
<tr>
<td>ProxySend</td>
<td>Forwards proxy requests</td>
</tr>
<tr>
<td>RAD2RAD</td>
<td>Prepares to send RADIUS proxy requests</td>
</tr>
<tr>
<td>ReplyDispatch</td>
<td>Translates the Interlink-Reply-Status attribute to an FSM event</td>
</tr>
<tr>
<td>ReplyPrep</td>
<td>Prepares to generate reply messages prior to post-processing policy</td>
</tr>
<tr>
<td>ReplySend</td>
<td>Generates reply messages after post-processing policy</td>
</tr>
<tr>
<td>RequestDispatch</td>
<td>Translates the Interlink-Proxy-Action attribute to an FSM event</td>
</tr>
<tr>
<td>SECURID</td>
<td>Performs authentication with a SecurID server</td>
</tr>
<tr>
<td>SIM-TripletFile</td>
<td>Retrieves user profiles from realm files based on the Request-Attribute-For-Search option which defaults to Real-Username. If the reply items contain a set of GSM-Triplet attributes then starting randomly in the list only the required number of GSM triplets will be returned.</td>
</tr>
<tr>
<td>SRV_STATUS</td>
<td>For Status-Server (Management-Poll) requests</td>
</tr>
<tr>
<td>TIMEOUT</td>
<td>Performs timeout logging and provides feedback to other actions that have pending events</td>
</tr>
<tr>
<td>TUNNELING</td>
<td>Encrypts Tunnel-Password and resolves hints from client</td>
</tr>
</tbody>
</table>
Predefined .fsm Files

The following FSM tables can be read by the `radiusd` program at RAD-Series Server startup:

<table>
<thead>
<tr>
<th>.fSM</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>radius.fsm</td>
<td>Basic functions. This is the default read by the RAD-Series Server at startup, unless another .fsm is specified.</td>
</tr>
<tr>
<td>logall.fsm</td>
<td>Logs all accounting messages in the format specified in the log.config file.</td>
</tr>
</tbody>
</table>

The default `radius.fsm` file is created from the predefined `/etc/opt/aaa/default.fsm` during RAD-Series Server installation. Unless you choose to use an alternate state table with the `'-f <fsmttable>'` startup option, always edit `radius.fsm` and have the `radiusd` program read `radius.fsm`. 
Managing RADIUS Sockets

The RAD-Series Server can listen for requests on a particular local IP address and port, or on multiple IP addresses and ports. Similarly the RAD-Series Server can proxy requests from a particular IP address and port, or proxy requests using different source IP addresses and ports for different servers.

Managing RADIUS Listen Sockets

The RAD-Series Server can open up to eight sockets on which to listen for authentication requests, and up to eight sockets on which to listen for accounting requests. By default, the RAD-Series Server will listen for authentication requests on one IPv4 socket and will listen for accounting requests on one IPv4 socket.

The RAD-Series Server is configured with a set of zero or more IPv4 addresses, and zero or more IPv6 addresses, on which to listen. Each listen IP address is further configured with one or two listen ports: an authentication port and/or an accounting port. The RAD-Series Server opens a separate listen socket for each IP address/Port pair. The RAD-Series Server may be configured to open only authentication ports and no accounting ports, or vice versa.

The listen sockets are configured as a set of radius_socket{} configuration blocks. See “RADIUS Listen Socket Properties” on page 214 for a detailed description of this configuration block.

For example, the following configuration would listen for IPv4 authentication and accounting requests on interface 192.168.2.2, and listen for IPv6 authentication requests (but not accounting requests) on interface 2001:abc::4.

```plaintext
radius_socket
{
    ipaddr 192.168.2.2
    authport 1812
    acctport 1813
}
radius_socket
{
    ipaddr 2001:abc::4
    authport 1812
}
```

The configured listen IP address can be a specific IPv4 address, a specific IPv6 address, the IPv4 ANY address [0.0.0.0], or the IPv6 ANY address [::]. If the IPv4 ANY address is specified, the RAD-Series Server will receive requests which are sent to any of its IPv4 interfaces. If the IPv6 ANY address is specified, the server will receive IPv4 and IPv6 requests which are sent to any of its interfaces. It is recommended that you configure specific IPv4 and IPv6 addresses instead of the IPv6 ANY address.

The following provides some details involved in the handling of the configured listen blocks: There are interactions with (x)inetd. The -p and -q parameters sometimes play a role. And the RAD-Series Server has a default behavior if no radius_socket{} blocks are configured:
The following describes the opening of authentication listen sockets, and of how the RAD-Series Server builds the internal list of authentication listen sockets. Opening of accounting listen sockets is done in a similar manner:

- The RAD-Series Server first checks if it has been started via (x)inetd. If so, the server temporarily remembers the port number opened by (x)inetd.
- If (x)inetd has started the RAD-Series Server, and if the port number opened by (x)inetd matches the default authentication port (usually specified via the 'p' command-line parameter) then the socket opened by (x)inetd is considered an authentication socket and is added to the server's (initially empty) set of authentication listen sockets.
- The RAD-Series Server then processes the list of ipaddr/authport pairs configured in the radius_socket{} blocks. For each such ipaddr/authport pair, the server checks if the authport matches the port number, if any, opened by (x)inetd. If so, the server concludes that a socket for listening on this ipaddr/authport has already been opened by (x)inetd, and so the server skips over the opening of that ipaddr/authport configuration. Otherwise the server binds a new socket to the specified ipaddr/authport, and adds the new socket to the list of authentication listen sockets. If the authport is configured with a value of zero, then the default authentication port, specified by the 'p' command-line parameters, is substituted.

A note on the above - If IPv6 is disabled and if the radius_socket{} block's ipaddr is an IPv6 address, then the ipaddr/authport for that radius_socket{} block is bypassed, and an appropriate logfile message is generated, indicating that the RAD-Series Server will not listen on the specified IPv6 interface.

- If, after processing the collection of zero or more radius_socket{} blocks, no authentication sockets have yet been opened, and if no radius_socket{} blocks (either accounting or authentication) have been configured, then the RAD-Series Server opens one authentication listen socket, using the IPv4 ANY address (0.0.0.0) as the local interface and the default authentication port (usually specified with “-p”) as the local authport. This is done for backwards compatibility with previous versions of the RAD-Series Server, which did not support radius_socket{} blocks. The reason for first checking that no radius_socket{} blocks of any kind, with neither authport nor acctport, are configured, is that this allows the server to be configured via radius_socket{} blocks as an authentication only or accounting only server.

- It is the configurer's responsibility to ensure that there are no ipaddr/authport conflicts (i.e. overlaps) in the collection of configured radius_socket{} blocks. If the RAD-Series Server, when opening a new listen socket, encounters a bind error, because the address/port is already in use, the server will terminate with an appropriate logfile message. This could happen, say, if radius_socket{ ipaddr 0.0.0.0 authport 1812 } and radius_socket{ ipaddr 192.168.3.25 authport 1812 } were both configured.

A note on IP Address/Port conflicts - If one configures two radius_socket{} blocks with the same listen authport, one for the IPv4 ANY address (0.0.0.0) and one for an IPv6 specific address (e.g. 2001:abc::4), this theoretically creates no conflicts. However some operating systems treat this as a conflict and fail with a “bind error” when opening the second socket. Therefore the RAD-Series Server will bypass any IPv4 and IPv6 address configurations found in radius_socket{} blocks which have the same port as the port opened by (x)inetd.
Managing RADIUS Proxying Sockets

The RAD-Series Server can open up to eight sockets on which to proxy requests to other RADIUS servers.

By default, the RAD-Series Server will open one proxying socket, for proxying IPv4 requests to IPv4 servers; this socket is opened with the IPv4 ANY address and an ephemeral port. If IPv6 is enabled (see “ipv6_enabled” on page 202), then by default the server will open a second proxying socket, for proxying IPv6 requests to IPv6 servers; this socket is opened with the IPv6 ANY address and an ephemeral port. Binding to the local ANY address causes the operating system to select the local IP address for proxied requests.

By configuration, this default behavior can be modified. If the OS-chosen source IP addresses are not acceptable, then a default specific IPv4 source address for proxied IPv4 requests can be explicitly configured with the default_source_ipv4_address parameter (see “default-source-ipv4-address” on page 200, and a default specific IPv6 source address for proxied IPv6 requests can be configured with the default_source_ipv6_address parameter (see “default-source-ipv6-address” on page 200). An example of configuration of these two parameters, located in the aaa.config file:

```
# Proxy IPv4 requests with this source IP address
default_source_ipv4_address  192.168.2.2

# Proxy IPv6 requests with this source IP address
default_source_ipv6_address  2001:abc::4
```

The RAD-Series Server can further be configured to utilize multiple IPv4 proxy sockets and multiple IPv6 proxy sockets. A given client (actually a RADIUS peer server in this case) can be configured with a source IP address and a source port for proxied requests to that client (see SrcIP in “clients” on page 229 which describes the SrcIP=<ipaddr>:port parameter of the clients file), and this client-specific IP address will override the default proxy source IP address. An example of configuration of this parameter, located in the clients file:

```
# Proxy requests to abc.com with:
#   a source IP address of 192.168.1.2 and a source port of 2222
abc.com aSecret type=PROXY srcip=[192.168.1.2]:2222
```

Closing and Reopening Listen Sockets and Proxy Sockets upon a HUP

The RAD-Series Server, when processing a HUP signal, will close all RADIUS listen sockets other than the (x)inetd opened socket (if any), and close all proxy sockets, then reread the configurations, and then open new listen and proxy sockets representing the (possibly-updated) configuration. There may or may not have been configuration changes affecting the set of listen IP address/ports and proxy IP address/ports, and IPv6 operation may or may not have been changed from enabled to disabled (or vice versa).
IPv6 Operation

The RAD-Series Server can always send and receive RADIUS messages via IPv4 packets. The RAD-Series Server can also send and receive RADIUS messages via IPv6 packets, though by default it does not do so. The following steps indicate how the RAD-Series Server can be configured to send and receive IPv6 RADIUS messages.

- There are some very preliminary steps not described here, such as updating one's local DNS with IPv6 mappings, and updating the RAD-Series Server's /etc/hosts file with local IPv6 address(es).
- Interlink Networks provides a utility for assessing a machine's readiness for IPv6 UDP communications. One should first run this readiness tool, and repair any revealed IPv6 deficiencies. See “The IPv6 Readiness Tool” on page 268 for details on this utility.
- The RAD-Series Server should be configured with IPv6 enabled. By default, IPv6 is disabled. See “The “ipv6_enabled” configuration parameter” on page 268 for details on what this means. Configure the server's aaa.config file with a “ipv6_enabled yes” parameter.
- Configure any IPv6 sockets on which the RADIUS server needs to listen for requests. See “Managing RADIUS Listen Sockets” on page 264 and “RADIUS Listen Socket Properties” on page 214.
- If the default IPv6 proxying behavior (by default, the source IPv6 address for proxied IPv6 requests is chosen by the OS, and the source port is ephemeral) is not adequate, then configure the IPv6 proxy sockets as needed. See “Managing RADIUS Proxying Sockets” on page 266.
- Configure any IPv6 clients and servers in the clients file. This can be done with the Server Manager as indicated in “Defining Access Devices” on page 41 and “Defining Proxies” on page 45. To manually edit them, see “clients” on page 229.
- Configure the RAD-Series Server to communicate with an LDAP server using TCP/IPv6, if desired. See “ProLDAP Authentication Type” on page 225.
- Start the RAD-Series Server. Check the server's logfile for any messages indicating a problem. Do a crude test of the server's configuration by having the radcheck utility send an IPv6 status request. See “radcheck” on page 110 for more details. The radcheck output should confirm that IPv6 is enabled. Do another crude test of the server's configuration by having the radpwtst utility send an IPv6 RADIUS request. See “radpwtst” on page 111 for more details.
The IPv6 Readiness Tool

Interlink Networks provides an “IPv6 Readiness Tool” utility for assessing a machine's readiness for IPv6 UDP communications. This utility is installed with the RAD-Series Server (/opt/aaa/bin/ipv6check/ipv6check.sh) and can be installed separately for testing. This tool checks:

- If the operating system is supported by the RAD-Series Server.
- If IPv6 support is enabled in the kernel.
- If certain utilities (ifconfig, route, netstat, ip, tcpdump) are IPv6-ready.
- If certain IPv6 utilities (ping6, tracepath6, traceroute6) are available.
- If the DNS infrastructure of the operating system is IPv6 ready.
- If a Link-Local address is configured, and if so, is pingable.
- If an IPv6 Link-Local route exists.
- If an IPv6 default route exists.
- If a specified IPv6 address is pingable.
- If the readiness tool's test server can bind to the [:] address
- If non-Link-Local IPv6 addresses are configured, and if so, if the readiness tool's test server can bind to the non-Link-Local IPv6 addresses.

The “ipv6_enabled” configuration parameter

The RAD-Series Server maintains a boolean configuration parameter which enables or disables sending and receiving RADIUS messages over UDP/IPv6. This parameter is initialized so that IPv6 communications are by-default disabled.

This “ipv6_enabled Yes/No” parameter is configured in the aaa.config file. When the RAD-Series Server reads the aaa.config file at startup, or when processing a HUP signal, the parameter's setting, initially off, is updated.

If IPv6 is disabled (ipv6_enabled=No), the RAD-Series Server will utilize only IPv4 sockets and internally call IPv4 only operating system routines. If enabled (ipv6_enabled=Yes), the server will open IPv6 sockets and call IPv6 operating system routines when needed.

The state of ipv6_enabled can be changed when re-reading aaa.config during HUP processing. The effect is that communications with IPv6 only clients will be shut down or opened up. This permits a quick disabling of IPv6 messages without extensive configuration changes: ipv6_enabled=No acts as a master IPv6 shutdown switch. If ipv6_enabled=No, then any clients which have only IPv6 addresses will be ignored. Any listen sockets configured with IPv6 addresses will not be opened. At startup and following a HUP, logfile messages are generated when IPv6 configuration pieces are being ignored.

The specific effects of ipv6_enabled are these:

- No matter whether ipv6_enabled is Yes or No:
• IP address fields in most data structures are of a size capable of holding either IPv4 or IPv6 addresses.

• The RAD-Series Server can send and receive IPv6-specific RADIUS attributes, such as NAP-IPv6-Address. These IPv6 related attributes, defined in RFC 3162: “RADIUS and IPv6”, are defined in the default dictionary.

• For IPv4 communications the RAD-Series Server will open IPv4 only sockets.

• Communications with the LDAP server are not under the control of the ipv6_enabled switch. So if the LDAP server name maps to an IPv6 address, or if the LDAP server is configured with an explicit IPv6 address, then the RAD-Series Server will send IPv6 messages to the LDAP server.

  • If ipv6_enabled is Yes:
    • IPv6 networking is additionally enabled. The RAD-Series Server will open IPv6 sockets for receiving and sending IPv6 messages. The server can communicate with IPv6 clients.
    • DNS lookups are done with an operating system routine which returns both IPv4 and IPv6 addresses.
  
  • If ipv6_enabled is No:
    • IPv6 networking is specifically disabled. The RAD-Series Server will not communicate with any peer which has only an IPv6 address.
    • DNS lookups are done with an operating system routine which returns only IPv4 addresses.
Configuring EAP-AKA

The configuration files must be edited manually as EAP-AKA cannot currently be configured using the Server Manager.

Configuration information for EAP-AKA is placed in several files, with some default values built into the RAD-Series Server. There is a precedence for the values that can be found in multiple places. The server starts with the built-in default values and overrides them with values in `aaa.config` (global values). The resulting values can be overridden by values in the `EAP.authfile` on a per realm basis. Finally the results of the user credential lookup may override some of these values.

Which file to configure a particular piece of information in is best made on the basis of where it will appear the least number of times. Based on this, the choice is first to use the `aaa.config` file, then `EAP.authfile`, and finally in the user credential datastore.

Some items would not be reasonable to configure on a global basis since they are user-specific, like the user password. These need to be unique, so the user credential datastore is the correct place for them. However some items, such as the AKA-Algorithm, may be common to all the users in a given realm so they could be configured in the `EAP.authfile` in just one place instead of each user’s entry in the datastore for that realm. If all the realms used the same AKA-Algorithm then putting the AKA-Algorithm in the `aaa.config` file would be the best option. These are just some basic guidelines for grouping the common values in the best place.

EAP-AKA Features

The Interlink EAP-AKA RAD-Series Server is fully compliant with RFC4187, 2006. The RFC’s “MUSTs”, “SHOULDs”, and “RECOMMENDEDs” are implemented. It supports the following features:

- IMSI permanent identities, supportable on a per realm basis
- Non-IMSI permanent identities, supportable on a per realm basis
- Protected success indications, supportable on a per realm basis
- Fast re-authentication, supportable on a per realm basis
- Protected Identity Exchanges using AT_CHECKCODE, supportable on a per realm basis
- Authentication Management Field (AMF) supportable on a per realm basis
- Pseudonym support via algorithmically generated or random pseudonyms, supportable on a per realm basis
- To ensure that permanent usernames, pseudonym usernames, and fast re-authentication usernames are separate and recognizable from each other, the RAD-Series Server generates pseudonyms with a leading “4” character and fast re-authentication usernames with a leading “5” character. Per the RFC, permanent usernames derived from the IMSI are prefixed with a leading “0” character.
- Many EAP-AKA parameters are configurable on a per realm basis
• A user's subscriber key (Ki), sequence number, mode, and the name of the appropriate AKA algorithms, may be stored in an external database or local file. If so, the RAD-Series Server will automatically generate the authentication vector from this information.
• An authentication vector may be stored in a local file. This is intended for use in a lab environment, and requires no additional user-written plug-ins.
• The user credentials may be retrieved from an AuC if the customer implements an AATV which communicates with the AuC.
• AKA 3GPP Milenage algorithms are provided with configurable parameters.
• The Milenage AKA algorithm can be customized with a simple plug-in.
• Additional customer supplied AKA algorithms may be plugged into the RAD-Series Server.
• Occurrences and values of received AKA attributes are validated.
• Support for pseudonym and fast reauthentication identity mapping is built-in, without the need of an external database.

**EAP-AKA User Credential Lookup Configuration**

The RAD-Series Server inherently supports configuration of EAP-AKA user credentials as Reply Items in two forms:

One form is the configuration of the user's **Subscriber-Key** (Ki), **AKA-Sequence-Number** (SQN), **AKA-Mode** (Authentication Management Field, AMF), and **AKA-Algorithm**. See “A3, A8 and AKA Algorithms” on page 310 for a description of the algorithm. The RAD-Series Server uses these AVPs as input to generate an authentication vector.

- **Subscriber-Key** is a string attribute containing the binary encoded 128-bit user secret key often referred to as Ki. The encoding should be in network byte order (big-endian).
- **AKA-Sequence-Number** is a string attribute containing the binary encoded 48-bit user sequence number often referred to as SQN. The encoding should be in network byte order (big-endian).
- **AKA-Mode** is a string attribute containing the binary encoded 16-bit user authentication management field often referred to as AMF. The encoding should be in network byte order (big-endian).
- **AKA-Algorithm** is a string attribute indicating the name of the AKA algorithm to be applied in AKA vector generation. Most lines in the configuration files are limited to 1023 characters which places a limit on the length of this string. The value is case-sensitive.

The second form is the configuration of an AKA vector. An **AKA-Vector** is a fixed length binary string (octets) attribute which holds an EAP-AKA authentication vector. The attribute value is a 576-bit binary string (72 bytes) partitioned as follows:

- **RAND** = The first 128 bits (16 bytes) of value
- **XRES** = The next 64 bits (8 bytes) of value
- **CK** = The next 128 bits (16 bytes) of value
- **IK** = The next 128 bits (16 bytes) of value
RAD-Series 8.1 Administrator’s Guide

•

AUTN =

The last 128 bits (16 bytes) of value

Configuration of an AKA-Vector is intended for a test lab environment, when the user's
Subscriber-Key, AKA-Sequence-Number, AKA-Mode, and AKA-Algorithm are not known but
AKA vectors have been retrieved from the device to be used in the testing.
The user credentials can be stored in any supported data repository: a local realm users file, a
LDAP database, or a customer supplied database.
Additionally, a customer-specific plug-in may provide EAP-AKA user credentials. This plug-in
may access a customer supplied database or may contact an authentication center. The plug-in's
Authentication-Type needs to be defined in the dictionary and may be configured with an
Xstring parameter in the authfile.
Example realm file content

The following is an example of a local realm users file. See “User Entry Syntax” on page 233 for
the a description of the format and allowable content. What follows are two EAP-AKA users with
reply items used to authenticate the user:
# IMSI configured with 128 bit Subscriber-Key, 16 bit AKA-Mode,
#
48 bit AKA-Sequence-Number, and AKA-Algorithm
801448005551000
Subscriber-Key
="\x6d\x37\x71\x8a\xcc\xec\x37\x01\x4e\xdb\xf0\xf0\x3b\xe5\x77\xda",
AKA-Mode = "\xa1\xb2",
AKA-Sequence-Number = "\x01\x02\x03\x04\x05\x06",
AKA-Algorithm = "3GPP-Milenage"
# Generic (i.e. non-IMSI permanent identity) user
# configured with a 576 bit AKA vector
fred
AKA-Vector="\x11\x11\x11\x11\x11\x11\x11\x11\x11\x11\x11\x11\x11\x12
\x22\x22\x22\x22\x22\x22\x22\x22\x22\x22\x22\x22\x22\x33\x33\x33\x33\x
33\x33\x33\x33\x33\x33\x33\x33\x33\x34\x44\x44\x44\x44\x44\x44\x44\x44
\x44\x44\x44\x44\x44\x55\x55\x55\x55\x55\x55\x55\x55\x55\x55\x55\x55\x
55\x55\x55\x55\x55\x55"

Note - Subscriber-Key, AKA-Mode, AKA-Sequence-Number and AKA-Vector values are binary
strings and are configured as quoted strings of hex escaped octets.
Note - If a user's Subscriber-Key is configured, but the AKA-Algorithm is not configured, the
default AKA-Algorithm specified in the realm's configuration or the globally configured value
will be used.

EAP-AKA Realm-Based Configurations
Many EAP-AKA parameters can be configured on a per realm basis. These parameters are
configured in realm entries stored in the authfile and EAP.authfile (these files are possibly
prefixed). The realm names may be wildcarded.

Interlink Networks, LLC.

Page 272


Realm-Based EAP-AKA Configuration Information in authfile

The user's AKA credentials lookup information is configured in the authfile on a realm by realm basis.

The EAP-AKA realm must be configured with the -AKA switch (the -AKA switch is new as of version 7.4), which shields this realm entry from undesired iaaaRealm actions.

If the realm utilizes a local users file, then the localFile AATV will be used.

localFile Authentication Type

The localFile AATV is an enhanced version of iaaaFile. Whereas iaaaFile always looks up the user record specified by the User-Id attribute value, localFile can search based on a specified attribute value. The configuration of a realm which employs localFile is followed by a required {} block. The {} block allows any or all of these three parameters: Request-Attribute-For-Search, Filter-Type, and Policy-Pointer. Another difference from iaaaFile is that the Filter-Type is not controlled by the -BIN and -CIS flags but by the Filter-Type specification in the {} block.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-Attribute-For-Search</td>
<td>This indicates the search attribute to use for a user lookup. The attribute must be a string-type (string, tag-str, octets). The localFile AATV is not restricted to use by EAP-AKA, it may be used generically. When localFile is used for EAP-AKA, the Request-Attribute-For-Search attribute must be configured with a value of Real-Username. The default value, if not present, is User-Id.</td>
</tr>
<tr>
<td>Filter-Type</td>
<td>This is used to specify case-sensitive or case-insensitive treatment of the value of the Request-Attribute-For-Search attribute. A value of &quot;BIN&quot; causes a case-sensitive lookup. A value of &quot;CIS&quot; causes a case-insensitive lookup performed by taking the contents of the attribute specified for searching and converting it to uppercase before the datastore lookup. Therefore the local realm file needs to store the identity in uppercase. The default value, if Filter-Type is not present, is BIN.</td>
</tr>
<tr>
<td>Policy-Pointer</td>
<td>For information on Policy-Pointer, see &quot;Authorization&quot; on page 8.</td>
</tr>
</tbody>
</table>

Example localFile authfile configuration for credentials lookup

```
# This realm uses a local realm users file "realm1.users"
eapakarealm1.com -AKA localFile realm1
{
    Request-Attribute-For-Search    Real-Username
}
```
# This set of wildcarded realms use realm users file "ispx.users"

*.*.ispx.com -AKA localFile ispx
{  
  Request-Attribute-For-Search Real-Username
}

## ProLDAP Authentication Type

The PROLDAP AATV has, as of version 7.3, been enhanced to support the Request-Attribute-For-Search configuration parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-Attribute-For-Search</td>
<td>This indicates the search attribute to use for a user lookup. The attribute must be a string-type (string, tag-str, octets). The default value, if not present, is User-Id. When PROLDAP is used for EAP-AKA, the Request-Attribute-For-Search attribute must be configured with a value of Real-Username.</td>
</tr>
</tbody>
</table>

### Example ProLDAP authfile configuration for credentials lookup

```
# This realm uses an LDAP database
eapakarealm3.com -AKA PROLDAP "LDAP lookup"
{  
  Request-Attribute-For-Search Real-Username
  Filter-Type CIS
  Directory "Directory 1"
  {  
    URL "ldap://ldap1.ispx.com:389"
    Administrator "cn=...,ou=...,ou=...,o=radius"
    Password "password"
    SearchBase "...,ou=...,o=radius"
    Authenticate Search
  }
}
```

See “ProLDAP Authentication Type” on page 274 for details on all the parameters.
Realm-Based EAP-AKA Configuration Information in EAP.authfile

The EAP.authfile entry for a realm which supports EAP-AKA can contain an optional {} configuration block following the ‘EAP-Type AKA’ specification. This block contains realm specific EAP-AKA configuration information. Some of these configuration lines are EAP-AKA parameters and the AATVs for lookup and update of pseudonym and fast reauthentication identity mappings. See “Pseudonym and Fast Re-Authentication Data Base AATVs” on page 315 for a description of the provided implementation.

Some of the parameters, if not specified in the EAP-Type AKA{} configuration block, will be assigned default values from the aatv.EAP-AKA{} configuration block in aaa.config. Other parameters do not have a default and must be specified if the capability is to be supported.

The following rules apply to the EAP-Type AKA{} configuration block parameters

- The parameter names are case insensitive.
- For parameters with on/off binary values, the values "enabled", "yes", "on", and "true" are synonyms and the values "disabled", "no", "off", and "false" are synonyms.
- String parameter values should be enclosed in single or double quotes.
- When configuring a lookup or update for a fast reauthentication identity or pseudonym, the configuration parsing requires that a string parameter must be specified. It may be an empty string, i.e. "". This string is used as the Xstring value for the lookup and update AATV calls. The Interlink provided AATVs do not require an Xstring and so the "" should be used. If a custom AATV is written for lookup or update then that AATV may require a string parameter. See the Software Developers Kit for more details on AATVs and Xstring.
- If there is no AATV for the lookup or update for a fast reauthentication identity or pseudonym, then the parameter (e.g. Fast-Reauth-Lookup) may be simply not configured at all. Alternatively, the configuration may be explicitly configured with an AATV value of "NULL" or "NONE".
- Pseudonym lookup is disabled if the realm's configuration specifies that pseudonyms should be algorithmically generated (i.e. "Generate-Random-Character-Pseudonyms No"), but NO pseudonym encryption keys are configured in the aatv.SIMAKA{} section of the aaa.config file.
- Generation of new pseudonyms is disabled if the realm's configuration specifies that pseudonyms should be generated but NO Pseudonym-Algorithm-Current-Key is configured in the aatv.SIMAKA{} section of the aaa.config file.

The EAP-Type AKA{} configuration block can contain any subset, including the empty subset, of
the following named parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AKA-Algorithm</td>
<td>This parameter specifies the default AKA Algorithm for the realm. If the</td>
</tr>
<tr>

<td>values are &quot;Enabled&quot; and &quot;Disabled&quot;. If not explicitly configured, the default</td>
</tr>
<tr>
<td></td>
<td>value is specified in the Prefixed-IMSI-Permanent-IDs parameter in the</td>
</tr>
<tr>
<td></td>
<td>aatv.EAP-AKA{} section of the aaa.config file.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Generic-Permanent-IDs</td>
<td>This parameter indicates whether or not the RAD-Series Server should, for this realm, accept generic permanent identities not based on an IMSI, e.g. &quot;fred&quot;. The EAP-AKA RFC 4187 indicates that the permanent identity SHOULD be derived from the IMSI, but alternatively, an implementation MAY choose a permanent identity that is not based on the IMSI. The server supports both options. The valid values are &quot;Enabled&quot; and &quot;Disabled&quot;. If not explicitly configured, the default value is specified in the Generic-Permanent-IDs parameter in the aatv.EAP-AKA{} section of the aaa.config file.</td>
</tr>
<tr>
<td>Minimum-Length-IMSI and</td>
<td>These parameters specify the minimum and maximum length of IMSIs that the RAD-Series Server will accept. The server performs sanity checks on a permanent identity that is offered as an IMSI to ensure that the identity is neither too short nor too long to be an IMSI. The EAP-AKA RFC 4187 explicitly states that 15 is the maximum. The minimum length is 6 based on a 3 digit MCC plus a 2 digit MNC plus a 1 digit MSIN. This is a theoretical absolute minimum length for an IMSI. Therefore the check made is: 6 &lt;= Minimum-Length-IMSI &lt;= Maximum-Length-IMSI &lt;= 15 If not explicitly configured, the default values are specified in the Minimum-Length-IMSI and Maximum-Length-IMSI parameters in the aatv.EAP-AKA{} section of the aaa.config file.</td>
</tr>
<tr>
<td>Maximum-Length-IMSI</td>
<td></td>
</tr>
<tr>
<td>Protected-Success-Indications</td>
<td>Protected success indications are an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter indicates whether the server will offer protected success indications to the peer. The valid values are &quot;Enabled&quot; and &quot;Disabled&quot;. If not explicitly configured, the default value is specified in the Protected-Success-Indications parameter in the aatv.EAP-AKA{} section of the aaa.config file.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Protected-Identity-Exchanges</td>
<td>The use of the AT_CHECKCODE attribute is an optional feature in EAP-AKA. This parameter determines if the RAD-Series Server should use the AT_CHECKCODE attribute. The attribute is used in order to allow protection of the EAP/AKA-Identity messages and any future extensions to them. The implementation of AT_CHECKCODE is RECOMMENDED. The valid values are &quot;Yes&quot; and &quot;No&quot;. If not explicitly configured, the default value is specified in the Protected-Identity-Exchanges parameter in the aatv.EAP-AKA{} section of the aaa.config file.</td>
</tr>
<tr>
<td>Resync-Update</td>
<td>The EAP-AKA protocol requires support for two features related to the management of sequence numbers (SQN). This parameter specifies an AATV which provides one of the features and an Xstring parameter for this AATV. This AATV is invoked to inform the authentication center (AuC) about synchronization failures. The reception of an EAP-Response/AKA/Synchronization-Failure message from the client will trigger the call to this AATV. This parameter does not need to be configured if your implementation does not require this feature. There is no default.</td>
</tr>
<tr>
<td>Auth-Result-Update</td>
<td>The EAP-AKA protocol requires support for two features related to the management of sequence numbers (SQN). This parameter specifies an AATV which provides one of the features and an Xstring parameter for this AATV. This AATV is invoked to inform the authentication center (AuC) about the results of an authentication attempt. The completion of an EAP-AKA authentication sequence (successful or not) will trigger the call to this AATV. This parameter does not need to be configured if your implementation does not require this feature. There is no default.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Fast-Reauth-Lookup</td>
<td>Fast re-authentication is an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter specifies an AATV and an Xstring parameter for this AATV. This AATV is invoked to map a fast reauthentication identity to the user's real identity and full authentication context. If this parameter is not configured, then fast re-authentication support is disabled for the realm. The Interlink server provides an AATV, SIMAKA-ReauthCacheLookup, for this function. See “Fast Re-Authentication” on page 317 for details. There is no default.</td>
</tr>
<tr>
<td>Fast-Reauth-Update</td>
<td>Fast re-authentication is an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter specifies an AATV and an Xstring parameter for this AATV. This AATV is invoked to update the mapping of a fast reauthentication identity to a user's real identity. If this parameter is not configured, then fast re-authentication support is disabled for the realm. The Interlink server provides an AATV, SIMAKA-ReauthCacheUpdate, for this function. See “Fast Re-Authentication” on page 317 for details. There is no default.</td>
</tr>
</tbody>
</table>
Pseudonym-Lookup

Pseudonyms are an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter specifies an AATV and an Xstring parameter for this AATV. This AATV is invoked to map a pseudonym to the user’s real identity.

If this parameter is not configured, then pseudonym support is disabled for the realm.

If this parameter specifies the Interlink-provided AATV SIMAKA-PseudonymDecrypt, see “Pseudonym” on page 315, then:

- The server forces non-random pseudonym generation for this realm.
- If no Pseudonym-Algorithm-Key-* parameters are defined in the aatv.SIMAKA{} section of the aaa.config file, then pseudonym support is disabled.
- If at least one of the above mentioned keys is defined and the Pseudonym-Algorithm-Current-Key is not defined in the aatv.SIMAKA{} section of the aaa.config file or does not refer to a defined key, then generation of new pseudonyms is disabled but existing pseudonyms can be looked up.

There is no default.

Pseudonym-Update

Pseudonyms are an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter specifies an AATV and an Xstring parameter for this AATV. This AATV is invoked to update the mapping of a pseudonym to a user’s real identity.

The Interlink provided pseudonym support using an algorithm, does not require an Pseudonym-Update AATV. See “Pseudonym” on page 315.

There is no default.

Max-Number-Of-Reauths-Before-Full-Auth-Is-Required

Fast re-authentication is an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter specifies an upper limit for the number of subsequent fast re-authentications allowed before a full authentication needs to be performed.

The valid range is 1 to 65,535.

If not explicitly configured, the default value is specified in the Max-Number-Of-Reauths-Before-Full-Auth-Is-Required parameter in the aatv.EAP-AKA{} section of the aaa.config file.
### Fast-Reauth-Realm

When providing a fast reauthentication identity, the RAD-Series Server also includes a realm to help ensure that the subsequent fast re-authentication be targeted to this server, the only server which holds the full authentication context if internal caching, rather than an external database, is used to save the fast re-authentication context.

This parameter specifies such a realm. Since the maximum length of a fast reauth NAI cannot exceed 253 characters and since the length of the fast reauth user name is 10 characters, the Fast Reauth Realm value must not exceed 242 characters. If the fast reauthentication identity should be generated with NO realm name then this would be configured as "NULL".

The empty string entry, using just two quotes, indicates that the server should generate a fast reauthentication identity with the same realm name as the permanent identity.

If not explicitly configured, the default value is specified in the `Fast-Reauth-Realm` parameter in the `aatv.EAP-AKA{}` section of the `aaa.config` file.

### Fast-Reauth-Id-Lifetime

Fast re-authentication is a mechanism for a AKA user to freshen his keys periodically. A fast re-authentication, if it is going to take place, will happen in a "short" time after a full authentication or a previous fast re-authentication. This parameter specifies a lifetime for a fast reauthentication identity, in seconds. If the fast reauthentication identity is assigned and isn't used within this period of time, the fast reauthentication identity and the associated full authentication context is purged.

The valid range is 1 to 14400 (1 second to 4 hours).

If not explicitly configured, the default value is specified in the `Fast-Reauth-Id-Lifetime` parameter in the `aatv.EAP-AKA{}` section of the `aaa.config` file.
Example EAP.authfile configuration file

The following EAP.authfile configures the EAP-AKA protocol for an AKA realm:

eapaka.com    -EAP      EAP      "comment"
{              
  EAP-Type AKA
  {               
    AKA-Algorithm    "3GPP-Milenage"
    Prefixed-IMSI-Permanent-IDs  "Enabled"
    Generic-Permanent-IDs        "Enabled"
    Minimum-Length-IMSI          6
    Maximum-Length-IMSI          15
    Protected-Success-Indications "Disabled"
    Protected-Identity-Exchanges No
    AKA-Mode                 0x12ab
    Resync-Update             null       "null"
    Auth-Result-Update         NULL        "none"
#                      Temporary identity datastores
Fast-Reauth-Lookup SIMAKA-ReauthCacheLookup ""
Fast-Reauth-Update SIMAKA-ReauthCacheUpdate ""
Pseudonym-Lookup SIMAKA-PseudonymDecrypt ""
Pseudonym-Update NULL ""

# Fast Reauth configuration:
Max-Number-Of-Reauths-Before-Full-Auth-Is-Required 2
Fast-Reauth-Realm "this.server.com"
Fast-Reauth-Id-Lifetime 3600

# Pseudonym configuration:
Pseudonym-Lifetime 1209600
Generate-Random-Character-Pseudonyms "No"
}
}

**Global EAP-AKA Configuration in aaa.config**

The `aatv.EAP-AKA{}` configuration block, located within the `aaa.config` file, contains global EAP-AKA configuration information. Some of the parameters represent realm default values for those not specified in the realm configuration. Other parameters represent global defaults which do not correspond to any realm based parameter. For the global parameters common to EAP-SIM and EAP-AKA, see “EAP-AKA and EAP-SIM Common Global Configurations” on page 288.

The following rules apply to the `aatv.EAP-AKA{}` configuration block parameters

- The parameter names are case insensitive.
- For parameters with on/off binary values, the values "enabled", "yes", "on", and "true" are synonyms and the values "disabled", "no", "off", and "false" are synonyms.
- String parameter values should be enclosed in single or double quotes.

The `aatv.EAP-AKA{}` configuration block, in `aaa.config` file, can contain any subset, including the empty subset, of the following named parameters:

**The following parameters are global. No realm configuration overrides.**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statistics</td>
<td>This parameter enables/disables the output of EAP-AKA statistics to the logfile when the RAD-Series Server shuts down. The valid values are &quot;Enabled&quot; and &quot;Disabled&quot;. If not explicitly configured, the default value is &quot;Enabled&quot;</td>
</tr>
</tbody>
</table>

**The following parameters specify RAD-Series Server-wide realm defaults.**
These are overridable by the realm configuration.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AKA-Algorithm</td>
<td>This parameter specifies the global default AKA Algorithm. If the profile for a user does not specify an AKA Algorithm and if the realm configuration does not specify an AKA Algorithm and if an AKA Algorithm is needed to produce the AKA Vector for this user's authentication, then the AKA Algorithm specified by this parameter is used. See “A3, A8 and AKA Algorithms” on page 310 for details on available algorithms. If not explicitly configured, there is NO default value.</td>
</tr>
<tr>
<td>AKA-Mode</td>
<td>AKA-Mode is the user authentication management field often referred to as AMF. It is an input to the functions f1 and f1*, See 3GPP documents for details. The value is a 16-bit binary string (2 bytes) entered as “0x” followed by 2 two digit hex values. “dots” are optional and are just for readability. The encoding should be in network byte order (big-endian). See examples below. If not explicitly configured, there is NO default value.</td>
</tr>
<tr>
<td>Prefixed-IMSI-Permanent-IDs</td>
<td>This parameter indicates whether or not the RAD-Series Server should accept permanent identities of the form '0' + IMSI for a realm, if the realm configuration does not specify this parameter. The EAP-AKA RFC 4187 indicates that the permanent identity SHOULD be derived from the IMSI, but alternatively, an implementation MAY choose a permanent identity that is not based on the IMSI. The valid values are &quot;Enabled&quot; and &quot;Disabled&quot;. If not explicitly configured, the default value is &quot;Enabled&quot;.</td>
</tr>
<tr>
<td>Generic-Permanent-IDs</td>
<td>This parameter indicates whether or not the RAD-Series Server should accept generic permanent identities not based on an IMSI, e.g. &quot;fred&quot;, for a realm where the realm configuration does not specify this parameter. The EAP-AKA RFC 4187 indicates that the permanent identity SHOULD be derived from the IMSI, but alternatively, an implementation MAY choose a permanent identity that is not based on the IMSI. The valid values are &quot;Enabled&quot; and &quot;Disabled&quot;. If not explicitly configured, the default value is &quot;Disabled&quot;.</td>
</tr>
</tbody>
</table>
**Minimum-Length-IMSI and Maximum-Length-IMSI**

These parameters specify the minimum and maximum length of IMSIs that the RAD-Series Server will accept.

The server performs sanity checks on a permanent identity that is offered as an IMSI to ensure that the identity is neither too short nor too long to be an IMSI. The EAP-AKA RFC 4187 explicitly states that 15 is the maximum. The minimum length is 6, based on a 3 digit MCC plus a 2 digit MNC plus a 1 digit MSIN. This is a theoretical absolute minimum length for an IMSI. Therefore the check made is:

\[
6 \leq \text{Minimum-Length-IMSI} \leq \text{Maximum-Length-IMSI} \leq 15
\]

If not explicitly configured, the default values are 6 and 15.

**Protected-Success-Indications**

Protected success indications are an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter indicates whether the server will offer protected success indications to the peer.

The valid values are "Enabled" and "Disabled".

If not explicitly configured, the default value is "Enabled".

**Protected-Identity-Exchanges**

The use of the AT_CHECKCODE attribute is an optional feature in EAP-AKA. This parameter determines if the RAD-Series Server should use the AT_CHECKCODE attribute. The attribute is used in order to allow protection of the EAP/AKA-Identity messages and any future extensions to them. The implementation of AT_CHECKCODE is RECOMMENDED.

The valid values are "Yes" and "No".

If not explicitly configured, the default value is Yes.

**Max-Number-Of-Reauths-Before-Full-Auth-Is-Required**

Fast re-authentication is an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter specifies an upper limit for the number of subsequent fast re-authentications allowed before a full authentication needs to be performed.

The valid range is 1 to 65,535.

If not explicitly configured, the default value is 4.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Protected-Identity-Exchanges</td>
<td>The use of the AT_CHECKCODE attribute is an optional feature in EAP-AKA. This parameter determines if the RAD-Series Server should use the AT_CHECKCODE attribute. The attribute is used in order to allow protection of the EAP/AKA-Identity messages and any future extensions to them. The implementation of AT_CHECKCODE is RECOMMENDED. The valid values are &quot;Yes&quot; and &quot;No&quot;. If not explicitly configured, the default value is Yes.</td>
</tr>
<tr>
<td>Max-Number-Of-Reauths-Before-Full-Auth-Is-Required</td>
<td>Fast re-authentication is an optional EAP-AKA feature which the Interlink EAP-AKA RAD-Series Server supports. This parameter specifies an upper limit for the number of subsequent fast re-authentications allowed before a full authentication needs to be performed. The valid range is 1 to 65,535. If not explicitly configured, the default value is 4.</td>
</tr>
</tbody>
</table>
When providing a fast reauthentication identity, the RAD-Series Server also includes a realm to ensure that the subsequent fast re-authentication be targeted to this server, the only server which holds the full authentication context if internal caching, rather than an external database, is used to save the fast re-authentication context.

This parameter specifies such a realm. Since the maximum length of a fast reauth NAI cannot exceed 253 characters and since the length of the fast reauthentication identity is 10 characters, the Fast Reauth Realm value must not exceed 242 characters. If the fast reauthentication identity should be generated with NO realm name then this would be configured as "NULL".

The empty string entry, using just two quotes, indicates that the server should generate a fast reauthentication identity with the same realm name as the permanent identity.

If not explicitly configured, the default value is the empty string entry which indicates the server should generate a fast reauthentication identity with the same realm name as the permanent identity.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fast-Reauth-Realm</td>
<td>When providing a fast reauthentication identity, the RAD-Series Server also includes a realm to ensure that the subsequent fast re-authentication be targeted to this server, the only server which holds the full authentication context if internal caching, rather than an external database, is used to save the fast re-authentication context. </tr>
<tr>
<td>Fast-Reauth-Id-Lifetime</td>
<td>Fast re-authentication is a mechanism for an EAP-AKA user to freshen his keys periodically. A fast re-authentication, if it is going to take place, will happen in a &quot;short&quot; time after a full authentication or a previous fast re-authentication. This parameter specifies a lifetime for a fast reauthentication identity, in seconds. If the fast reauthentication identity is assigned and isn't used for this period of time, the fast reauthentication identity and the associated full auth context is purged. The valid range is 1 to 14400 (1 second to 4 hours). If not explicitly configured, the default value is 3600 (one hour).</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Generate-Random-Character-Pseudonyms</td>
<td>Pseudonyms can be generated as an encrypted form of the permanent identity, which can be subsequently decrypted to reproduce the permanent identity. Alternatively, pseudonyms can be generated as a string of random characters, similar to the fast reauthentication identity. In this case, an external database is required to store the pseudonym to permanent identity mappings. This parameter indicates whether the RAD-Series Server generates pseudonyms by algorithm (value=&quot;no&quot;) or if the server generates random character pseudonyms (value=&quot;yes&quot;). The valid values are &quot;Yes&quot; and &quot;No&quot;. If not explicitly configured, the default value is &quot;No&quot;.</td>
</tr>
<tr>
<td>Pseudonym-Lifetime</td>
<td>A random character pseudonym, when generated for a user, is placed in an external database. This parameter specifies the lifetime of such a generated random character pseudonym. After the specified length of time has elapsed since the pseudonym was first assigned, the pseudonym is invalidated, independent of how many times the pseudonym was used, if ever used. The valid range is 1 to 31,622,400 (1 second to 366 days). If not explicitly configured, the default value is 1,209,600 (14 days).</td>
</tr>
</tbody>
</table>

### EAP-AKA and EAP-SIM Common Global Configurations

Some parameters common to EAP-AKA and EAP-SIM can ONLY be configured on a global basis. These parameters are configured in the `aatv.SIMAKA{}` configuration block, located within the `aaa.config` file. These parameters represent global defaults which do not correspond to any realm based parameter.

The following rules apply to the `aatv.SIMAKA{}` configuration block parameters:

- The parameter names are case insensitive.
- For parameters with on/off binary values, the values "enabled", "yes", "on", and "true" are synonyms and the values "disabled", "no", "off", and "false" are synonyms.
- String parameter values should be enclosed in single or double quotes.

The `aatv.SIMAKA{}` configuration block, in `aaa.config` file, can contain any subset, including the empty subset, of the following named parameters:
The following parameters are global. There are no realm based configuration overrides.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum-Fast-Reauth-Cache-Size</td>
<td>This parameter specifies the maximum size of the in-memory Fast Re-authentication table, in terms of the number of entries. For a given user, the RAD-Series Server needs to save the full authentication context for subsequent fast re-authentications. A bound must be placed on the number of entries in this table to protect the server’s memory. The valid range is 0 to 1,000,000. A value of zero means that no new fast reauth identities should be added to the cache, but existing non-expired entries will be honored. This value is intended to phase out fast reauth support following a HUP. If not explicitly configured, the default value is the number of licensed users up to a maximum of 1,000,000.</td>
</tr>
<tr>
<td>Pseudonym-Algorithm-Key-n</td>
<td>Pseudonyms can be generated as an encrypted form of the permanent identity, which can be subsequently decrypted to reproduce the permanent identity. This set of parameters (n = 1 to 16) can be used to specify up to 16 encryption keys that can be used for this encryption/decryption. The key value is a 128-bit binary string (16 bytes) entered as “0x” followed by 16 two digit hex values. “dots” are optional and are just for readability. See examples below. Pseudonym generation will be disabled for a realm if no keys have been defined and the generation of random character pseudonyms is disabled (Generate-Random-Character-Pseudonyms &quot;no&quot;). If not explicitly configured, there are NO default values.</td>
</tr>
<tr>
<td>Pseudonym-Algorithm-Current-Key</td>
<td>The key number specified by this parameter is used to select the Pseudonym-Algorithm-Key to use to encrypt the permanent identity when generating a new pseudonym. The other keys are used for decryption of pseudonyms previously generated with the other keys, but are not used for generation of new pseudonyms. The valid range is 1 to 16. If not explicitly configured, there is NO default value.</td>
</tr>
<tr>
<td>Statistics</td>
<td>This parameter enables/disables the output of common SIM and AKA statistics to the logfile when the RAD-Series Server shuts down. The valid values are &quot;Enabled&quot; and &quot;Disabled&quot;. If not explicitly configured, the default value is &quot;Enabled&quot;</td>
</tr>
</tbody>
</table>
Example aaa.config configuration file

```
aatv.SIMAKA
{
    # The following parameters are global.
    # They apply to the shared features of EAP-SIM and EAP-AKA.
    # There are no realm configuration overrides.
    #
    Maximum-Fast-Reauth-Cache-Size   4096       # range [0 to 1,000,000]
    Pseudonym-Algorithm-Key-1    0x00010203.04050607.08090a0b.0c0d0e0f
    Pseudonym-Algorithm-Key-11   0xa0a1a2a3.a4a5a6a7.a8a9aaab.acad0e0f
    Pseudonym-Algorithm-Key-16   0xf0f1f2f3.f4f5f6f7.f8f9fafb.fcfdfeff
    Pseudonym-Algorithm-Current-Key 11
    Statistics                       "Enabled"  # Enabled or Disabled
}
```
Configuring EAP-SIM

The configuration files must be edited manually as EAP-SIM cannot currently be configured using the Server Manager.

Configuration information for EAP-SIM is placed in several files, with some default values built into the RAD-Series Server. There is a precedence for the values that can be found in multiple places. The server starts with the built-in default values and overrides them with values in `aaa.config` (global values). The resulting values can be overridden by values in the `EAP.authfile` on a per realm basis. Finally, the results of the user credential lookup may override some of these values.

Which file to configure a particular piece of information in is best made on the basis of where it will appear the least number of times. Based on this, the choice is first to use the `aaa.config` file, then `EAP.authfile`, and finally in the user credential datastore.

Some items would not be reasonable to configure on a global basis since they are user-specific, like the user password. These need to be unique, so the user credential datastore is the correct place for them. However, some items, such as the A8-Algorithm, may be common to all the users in a given realm so they could be configured in the `EAP.authfile` in just one place instead of each user’s entry in the datastore for that realm. If all the realms used the same A8-Algorithm then putting the A8-Algorithm in the `aaa.config` file would be the best option. These are just some basic guidelines for grouping the common values in the best place.

EAP-SIM Features

The Interlink EAP-SIM RAD-Series Server is fully compliant with RFC4186, 2006. The RFC’s “MUSTs” “SHOULDs”, and “RECOMMENDEDs” are implemented. It supports the following features:

- IMSI permanent identities, supportable on a per realm basis
- Non-IMSI permanent identities, supportable on a per realm basis
- Protected success indications, supportable on a per realm basis
- Fast re-authentication, supportable on a per realm basis
- Pseudonym support via algorithmically generated or random pseudonyms, supportable on a per realm basis
- To ensure that permanent usernames, pseudonym usernames, and fast re-authentication usernames are separate and recognizable from each other, the RAD-Series Server generates pseudonyms with a leading “2” character and fast re-authentication usernames with a leading “3” character. Per the RFC, permanent usernames derived from the IMSI are prefixed with a leading “1” character.
- Many EAP-SIM parameters are configurable on a per realm basis
- A user's subscriber key (Ki), along with the names of the appropriate A3 and A8 algorithms, may be stored in an external database or local file. If so, the RAD-Series Server will automatically generate GSM authentication triplets from this information.
• A set of GSM authentication triplets may be stored in a local file. This is intended for use in a lab environment, and requires no additional user-written plug-ins.
• The user credentials may be retrieved from an AuC if the customer implements an AATV which communicates with the AuC.
• A3/A8 3GPP Milenage algorithms are provided with configurable parameters.
• The Milenage A3/A8 algorithm can be customized with a simple plug-in.
• Additional customer supplied A3/A8 algorithms may be plugged into the RAD-Series Server.
• Occurrences and values of received SIM attributes are validated.
• Support for pseudonym and fast reauthentication identity mapping is built-in, without the need of an external database.

**EAP-SIM User Credential Lookup Configuration**

The RAD-Series Server inherently supports configuration of EAP-SIM user credentials as Reply Items in two forms:

One form is the configuration of the user's **Subscriber-Key** ($K_i$), **A3-Algorithm** and **A8-Algorithm**. See “A3, A8 and AKA Algorithms” on page 310 for a description. The RAD-Series Server uses these AVPs as input to generate authentication vectors.

- **Subscriber-Key** is a string attribute containing the binary encoded 128-bit user secret key often referred to as $K_i$. The encoding should be in network byte order (big-endian).
- **A3-Algorithm** is a string attribute indicating the name of the A3 algorithm to be applied in GSM triplet generation. Most lines in the configuration files are limited to 1023 characters which places a limit on the length of this string. The value is case-sensitive.
- **A8-Algorithm** is a string attribute indicating the name of the A8 algorithm to be applied in GSM triplet generation. Most lines in the configuration files are limited to 1023 characters which places a limit on the length of this string. The value is case-sensitive.

The second form is the configuration of a collection of GSM triplets. A **GSM-Triplet** is a fixed length binary string (octets) attribute which holds an EAP-SIM authentication vector. The attribute value is a 224-bit binary string (28 bytes) partitioned as follows:

- **RAND** = The first 128 bits (16 bytes) of value
- **Kc** = The next 64 bits (8 bytes) of value
- **SRES** = The last 32 bits (4 bytes) of value

Configuration of GSM triplets is intended for a test lab environment, when the user's **Subscriber-Key**, **A3-Algorithm**, and **A8-Algorithm** are not known but GSM triplets have been retrieved from the device to be used in the testing.

The user credentials can be stored in any supported data repository: a local realm users file, an LDAP database, or a customer supplied database.

Additionally, a customer-specific plug-in may provide EAP-SIM user credentials. This plug-in may access a customer supplied database or may contact an authentication center. The plug-in's
Authentication-Type needs to be defined in the dictionary and may be configured with an Xstring parameter in the authfile.

Example realm file content

The following is an example of a local realm users file. See “User Entry Syntax” on page 233 for the a description of the format allowable content. What follows are two EAP-SIM users with reply items used to authenticate the user:

```
# IMSI configured with 128 bit Subscriber-Key, A3-Algorithm, and A8-Algorith
80144800551000
  Subscriber-Key = "\x6d\x37\x71\x8a\xc6\xe3\x37\x01\x4e\xd0\x0f\x3b\xe5\x77\xda",
  A3-Algorithm = "3GPP-Milenage",
  A8-Algorithm = "3GPP-Milenage"

# Generic (i.e. non-IMSI permanent identity) user
# configured with a collection of 224 bit triplets
fred
  GSM-Triplet="\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1
a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a\x1a",
  GSM-Triplet="\x2b\x2b\x2b\x2b\x2b\x2b\x2b\x2b\x2b\x2b\x2b\x2b\x2b\x2b\x2b",

Note - Subscriber-Key and GSM-Triplet values are binary strings and are configured as quoted strings of hex escaped octets.

Note - If a user's Subscriber-Key is configured, but the A3-Algorithm and/or A8-Algorithm is not configured, the default A3-Algorithm and/or A8-Algorithm specified in the realm's configuration or the globally configured value will be used.

Note - Under some conditions more GSM triplets may be configured than are necessary for a user's authentication and the RAD-Series Server will select the necessary number of GSM triplets from the collection in a manner described in “Realm-Based EAP-SIM Configuration Information in authfile” on page 295.
EAP-SIM Realm-Based Configurations

Many EAP-SIM parameters can be configured on a per realm basis. These parameters are configured in realm entries stored in the authfile and EAP.authfile (these files are possibly prefixed). The realm names may be wildcarded.
Realm-Based EAP-SIM Configuration Information in authfile

The user's SIM credentials lookup information is configured in the authfile on a realm by realm basis.

The EAP-SIM realm must be configured with the -SIM switch (the -SIM switch is new as of version 7.3), which shields the realm from undesired iaaaRealm actions.

If the realm utilizes a local users file, then one of the two new (as of version 7.3) AATVs should be used: localFile or SIM-TripletFile.

localFile Authentication Type

The localFile AATV is an enhanced version of iaaafile. Whereas iaaafile always looks up the user record specified by the User-Id attribute value, localFile can search based on a specified attribute value. The configuration of a realm which employs localFile is followed by a required {} block. The {} block allows any or all of these three parameters: Request-Attribute-For-Search, Filter-Type, and Policy-Pointer.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-Attribute-For-Search</td>
<td>This indicates the search attribute to use for a user lookup. The attribute must be a string-type (string, tag-str, octets). The localFile AATV is not restricted to use by EAP-SIM, it may be used generically. When localFile is used for EAP-SIM, the Request-Attribute-For-Search attribute must be configured with a value of Real-Username. The default value, if not present, is User-Id.</td>
</tr>
<tr>
<td>Filter-Type</td>
<td>This is used to specify case-sensitive or case-insensitive treatment of the value of the Request-Attribute-For-Search attribute. A value of &quot;BIN&quot; causes a case-sensitive lookup. A value of &quot;CIS&quot; causes a case-insensitive lookup performed by taking the contents of the attribute specified for searching and converting it to uppercase before the datastore lookup. Therefore the local realm file needs to store the identity in uppercase. The default value, if Filter-Type is not present, is BIN.</td>
</tr>
<tr>
<td>Policy-Pointer</td>
<td>For information on Policy-Pointer, see “Authorization” on page 8.</td>
</tr>
</tbody>
</table>

When localFile retrieves GSM triplets, there may be more configured triplets than are necessary for the user authentication. The EAP-SIM AATV will use the first $N$ retrieved triplets, where $N$ is the number of triplets this realm requires for a EAP-SIM authentication (i.e. either 2 or 3).

Example localFile authfile configuration for credentials lookup
# This realm uses a local realm users file "realm1.users"
eapsimrealm1.com  -SIM  localFile  realm1
{  
  Request-Attribute-For-Search  Real-Username  
}

# This set of wildcarded realms use realm users file "ispx.users"
*.ispx.com  -SIM  localFile  ispx
{  
  Request-Attribute-For-Search  Real-Username  
}

**SIM-TripletFile Authentication Type**

The **SIM-TripletFile AATV** is very similar to **localFile** with an identical {} block, but is specialized for the retrieval of **GSM-Triplet** credentials.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-Attribute-For-Search</td>
<td>This indicates the search attribute to use for a user lookup. The attribute must be a string-type (string, tag-str, octets). The default value, if not present, is Real-Username.</td>
</tr>
</tbody>
</table>
| Filter-Type             | This is used to specify case-sensitive or case-insensitive treatment of the value of the Request-Attribute-For-Search attribute.  
                          | A value of "BIN" causes a case-sensitive lookup.  
                          | A value of "CIS" causes a case-insensitive lookup performed by taking the contents of the attribute specified for searching and converting it to uppercase before the datastore lookup. Therefore the local realm file needs to store the identity in uppercase.  
                          | The default value, if Filter-Type is not present, is BIN.                                                                                                                                                  |
| Policy-Pointer          | For information on Policy-Pointer, see “Authorization” on page 8.                                                                                                                                               |

If **SIM-TripletFile** retrieves **GSM-Triplets** and if there are more configured triplets than are necessary for the user authentication, then **SIM-TripletFile** will return \( N \) configured triplets, where \( N \) is the number of triplets this realm requires for a SIM authentication. Rather than returning the first \( N \) triplets, **SIM-TripletFile** will pick a random starting point in the list of configured triplets and return the next \( N \) triplets, starting at the random starting point and wrapping to the beginning of the list if necessary.

If the datastore will be returning **GSM-Triplets**, then the use **SIM-TripletFile** would be the first choice. If you need a predicable set of **GSM-Triplets**, then use **localFile**.

**Example SIM-TripletFile authfile configuration for credentials lookup**
# This realm uses a local realm users file "realm2.users"
eapsimrealm2.com   -SIM   SIM-TripletFile   realm2
{
  Filter-Type                     CIS
  Request-Attribute-For-Search   Real-Username
  Policy-Pointer                  "decisionfile://policy-1.policy"
}

ProLDAP Authentication Type

The PROLDAP AAVT has, as of version 7.3, been enhanced to support the
Request-Attribute-For-Search configuration parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request-Attribute-For-Search</td>
<td>This indicates the search attribute to use for a user lookup. The attribute</td>
</tr>
<tr>
<td></td>
<td>must be a string-type (string, tag-str, octets). The default value, if not</td>
</tr>
<tr>
<td></td>
<td>present, is User-Id. When PROLDAP is used for EAP-SIM, the Request-Attribute-For-Search attribute must be configured with a value of Real-Username.</td>
</tr>
</tbody>
</table>

Example ProLDAP authfile configuration for credentials lookup

# This realm uses an LDAP database
eapsimrealm3.com   -SIM   PROLDAP   "LDAP lookup"
{
  Request-Attribute-For-Search   Real-Username
  Filter-Type                     CIS
  Directory   "Directory 1"
  {
    URL             "ldap://ldap1.ispx.com:389
    Administrator   "cn=...,ou=...,ou=...,o=radius"
    Password        "password"
    SearchBase      "...,ou=...,o=radius"
    Authenticate    Search
  }
}

See “ProLDAP Authentication Type” on page 274 for details on all the parameters.
Realm-Based EAP-SIM Configuration Information in EAP.authfile

The EAP.authfile entry for a realm which supports EAP-SIM can contain an optional {} configuration block following the ‘EAP-Type SIM’ specification. This block contains realm specific EAP-SIM configuration information: EAP-SIM parameters and the AATVs for lookup and update of pseudonym and fast reauthentication identity mappings. See “Pseudonym and Fast Re-Authentication Data Base AATVs” on page 315 for a description of the provided implementation.

Some of the parameters, if not specified in the EAP-Type SIM{} configuration block, will be assigned default values from the aatv.EAP-SIM{} configuration block in aaa.config. Other parameters do not have a default and must be specified if the capability is to be supported.

The following rules apply to the EAP-Type SIM{} configuration block parameters

- The parameter names are case insensitive.
- For parameters with on/off binary values, the values "enabled", "yes", "on", and "true" are synonyms and the values "disabled", "no", "off", and "false" are synonyms.
- String parameter values should be enclosed in single or double quotes.
- When configuring a lookup or update for a fast reauthentication identity or pseudonym, the configuration parsing requires that a string parameter must be specified. It may be an empty string, i.e. "". This string is used as the Xstring value for the lookup and update AATV calls. The Interlink provided AATVs do not require an Xstring and so the "" should be used. If a custom AATV is written for lookup or update then that AATV may require a string parameter. See the Software Developers Kit for more details on AATVs and Xstring.
- If there is no AATV for the lookup or update for a fast reauthentication identity or pseudonym, then the parameter (e.g. Fast-Reauth-Lookup) may be simply not configured at all. Alternatively, the configuration may be explicitly configured with an AATV value of "NULL" or "NONE".
- Pseudonym lookup is disabled if the realm's configuration specifies that pseudonyms should be algorithmically generated (i.e. "Generate-Random-Character-Pseudonyms No"), but NO pseudonym encryption keys are configured in the aatv.SIMAKA{} section of the aaa.config file.
- Generation of new pseudonyms is disabled if the realm’s configuration specifies that pseudonyms should be generated but no Pseudonym-Algorithm-Current-Key is configured in the aatv.SIMAKA{} section of the aaa.config file.

The EAP-Type SIM{} configuration block can contain any subset, including the empty subset, of
the following named parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A3-Algorithm</td>
<td>This parameter specifies the default A3 Algorithm for the realm. If the profile for a user in this realm does not specify an A3 Algorithm and if an A3 Algorithm is needed to produce the GSM triplets for this user's authentication, then the A3 Algorithm specified by this parameter is used. See “A3, A8 and AKA Algorithms” on page 310 for details on available algorithms. If not explicitly configured, the default value is specified in the A3-Algorithm parameter in the aatv.EAP-SIM{} section of the aaa.config file.</td>
</tr>
<tr>
<td>A8-Algorithm</td>
<td>This parameter specifies the default A8 Algorithm for the realm. If the profile for a user in this realm does not specify an A8 Algorithm and if an A8 Algorithm is needed to produce the GSM triplets for this user's authentication, then the A8 Algorithm specified by this parameter is used. See “A3, A8 and AKA Algorithms” on page 310 for details on available algorithms. If not explicitly configured, the default value is specified in the A8-Algorithm parameter in the aatv.EAP-SIM{} section of the aaa.config file.</td>
</tr>
<tr>
<td>Prefixed-IMSI-Permanent-IDs</td>
<td>This parameter indicates whether or not the RAD-Series Server should, for this realm, accept permanent identities of the form '1' + IMSI. The EAP-SIM RFC 4186 indicates that the permanent identity SHOULD be derived from the IMSI, but alternatively, an implementation MAY choose a permanent identity that is not based on the IMSI. The server supports both options. The valid values are &quot;Enabled&quot; and &quot;Disabled&quot;. If not explicitly configured, the default value is specified in the Prefixed-IMSI-Permanent-IDs parameter in the aatv.EAP-SIM{} section of the aaa.config file.</td>
</tr>
</tbody>
</table>
**Parameter** | **Description**
--- | ---
Generic-Permanent-IDs | This parameter indicates whether or not the RAD-Series Server should, for this realm, accept generic permanent identities not based on an IMSI, e.g. "fred". The EAP-SIM RFC 4186 indicates that the permanent identity SHOULD be derived from the IMSI, but alternatively, an implementation MAY choose a permanent identity that is not based on the IMSI. The server supports both options. The valid values are "Enabled" and "Disabled". If not explicitly configured, the default value is specified in the Generic-Permanent-IDs parameter in the aatv.EAP-SIM{} section of the aaa.config file.

Minimum-Length-IMSI and Maximum-Length-IMSI | These parameters specify the minimum and maximum length of IMSIs that the RAD-Series Server will accept. The server performs sanity checks on a permanent identity that is offered as an IMSI to ensure that the identity is neither too short nor too long to be an IMSI. The EAP-SIM RFC 4186 explicitly states that 15 is the maximum. The minimum length is 6 based on a 3 digit MCC plus a 2 digit MNC plus a 1 digit MSIN. This is a theoretical absolute minimum length for an IMSI. Therefore the check made is:

$$6 \leq \text{Minimum-Length-IMSI} \leq \text{Maximum-Length-IMSI} \leq 15$$

If not explicitly configured, the default values are specified in the Minimum-Length-IMSI and Maximum-Length-IMSI parameters in the aatv.EAP-SIM{} section of the aaa.config file.

Number-Of-Triplets-For-Authentication | This parameter indicates how many GSM triplets are needed for authentication. The EAP-SIM RFC 4186 indicates this value MUST be 2 or 3. If not explicitly configured, the default value is specified in the Number-Of-Triplets-For-Authentication parameter in the aatv.EAP-SIM{} section of the aaa.config file.

Protected-Success-Indications | Protected success indications are an optional EAP-SIM feature which the Interlink EAP-SIM RAD-Series Server supports. This parameter indicates whether the server will offer protected success indications to the peer. The valid values are "Enabled" and "Disabled". If not explicitly configured, the default value is specified in the Protected-Success-Indications parameter in the aatv.EAP-SIM{} section of the aaa.config file.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| Fast-Reauth-Lookup | Fast re-authentication is an optional EAP-SIM feature which the Interlink EAP-SIM RAD-Series Server supports. This parameter specifies an AATV and an Xstring parameter for this AATV. This AATV is invoked to map a fast reauthentication identity to the user's real identity and full authentication context.  
  
  If this parameter is not configured, then fast re-authentication support is disabled for the realm.  
  
  The Interlink server provides an AATV, SIMAKA-ReauthCacheLookup, for this function. See “Fast Re-Authentication” on page 317 for details.  
  
  There is no default. |
| Fast-Reauth-Update | Fast re-authentication is an optional EAP-SIM feature which the Interlink EAP-SIM RAD-Series Server supports. This parameter specifies an AATV and an Xstring parameter for this AATV. This AATV is invoked to update the mapping of a fast reauthentication identity to a user's real identity.  
  
  If this parameter is not configured, then fast re-authentication support is disabled for the realm.  
  
  The Interlink server provides an AATV, SIMAKA-ReauthCacheUpdate, for this function. See “Fast Re-Authentication” on page 317 for details.  
  
  There is no default. |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pseudonym-Lookup</td>
<td>Pseudonyms are an optional EAP-SIM feature which the Interlink EAP-SIM RAD-Series Server supports. This parameter specifies an AATV and an Xstring parameter for this AATV. This AATV is invoked to map a pseudonym to the user’s real identity. If this parameter is not configured, then pseudonym support is disabled for the realm. If this parameter specifies the Interlink-provided AATV SIMAKA-PseudonymDecrypt, see “Pseudonym” on page 315, then:   * The server forces non-random pseudonym generation for this realm.   * If no Pseudonym-Algorithm-Key-* parameters are defined in the aatv.SIMAKA{} section of the aaa.config file, then pseudonym support is disabled.   * If at least one of the above mentioned keys is defined and the Pseudonym-Algorithm-Current-Key is not defined in the aatv.SIMAKA{} section of the aaa.config file or does not refer to a defined key, then generation of new pseudonyms is disabled but existing pseudonyms can be looked up. There is no default.</td>
</tr>
<tr>
<td>Pseudonym-Update</td>
<td>Pseudonyms are an optional EAP-SIM feature which the Interlink EAP-SIM RAD-Series Server supports. This parameter specifies an AATV and an Xstring parameter for this AATV. This AATV is invoked to update the mapping of a pseudonym to a user’s real identity. The Interlink provided pseudonym support using an algorithm, does not require an Pseudonym-Update AATV. See “Pseudonym” on page 315. There is no default.</td>
</tr>
<tr>
<td>Max-Number-Of-Reauths-Before-Full-Auth-Is-Required</td>
<td>Fast re-authentication is an optional EAP-SIM feature which the Interlink EAP-SIM RAD-Series Server supports. This parameter specifies an upper limit for the number of subsequent fast re-authentications allowed before a full authentication needs to be performed. The valid range is 1 to 65,535. If not explicitly configured, the default value is specified in the Max-Number-Of-Reauths-Before-Full-Auth-Is-Required parameter in the aatv.EAP-SIM{} section of the aaa.config file.</td>
</tr>
</tbody>
</table>
When providing a fast reauthentication identity, the RAD-Series Server also includes a realm to help ensure that the subsequent fast re-authentication be targeted to this server, the only server which holds the full authentication context if internal caching, rather than an external database, is used to save the fast re-authentication context.

This parameter specifies such a realm. Since the maximum length of a fast reauth NAI cannot exceed 253 characters and since the length of the fast reauth user name is 10 characters, the Fast Reauth Realm value must not exceed 242 characters. If the fast reauthentication identity should be generated with NO realm name then this would be configured as "NULL".

The empty string entry, using just two quotes, indicates that the server should generate a fast reauthentication identity with the same realm name as the permanent identity.

If not explicitly configured, the default value is specified in the Fast-Reauth-Realm parameter in the aatv.EAP-SIM{} section of the aaa.config file.

Fast re-authentication is a mechanism for an EAP-SIM user to freshen his keys periodically. A fast re-authentication, if it is going to take place, will happen in a "short" time after a full authentication or a previous fast re-authentication. This parameter specifies a lifetime for a fast reauthentication identity, in seconds. If the fast reauthentication identity is assigned and isn’t used within this period of time, the fast reauthentication identity and the associated full authentication context is purged.

The valid range is 1 to 14400 (1 second to 4 hours).

If not explicitly configured, the default value is specified in the Fast-Reauth-Id-Lifetime parameter in the aatv.EAP-SIM{} section of the aaa.config file.
The Interlink RAD-Series Server provides a mechanism, using configured encryption keys, by which pseudonyms can be generated as an encrypted form of the permanent identity, which can be subsequently decrypted to reproduce the permanent identity. Alternatively, the server can generate pseudonyms as a string of random characters, similar to the fast reauthentication identity. In this latter case, an external database is required to store the pseudonym to permanent identity mappings.

This parameter indicates whether the server generates pseudonyms by algorithm (value=no) or if the server generates random character pseudonyms (value=yes).

The valid values are "Yes" and "No".

If not explicitly configured, the default value is specified in the Generate-Random-Character-Pseudonyms parameter in the aatv.EAP-SIM{} section of the aaa.config file.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Pseudonym-Lifetime</td>
<td>A random character pseudonym, when generated for a user, is placed in an external database. This parameter specifies the lifetime of such a generated random character pseudonym. After the specified length of time has elapsed since the pseudonym was first assigned, the pseudonym is invalidated, independent of how many times the pseudonym was used, if ever. The valid range is 1 to 31,622,400 (1 second to 366 days). If not explicitly configured, the default value is specified in the Pseudonym-Lifetime parameter in the aatv.EAP-SIM{} section of the aaa.config file.</td>
</tr>
</tbody>
</table>
Example EAP.authfile configuration file

The following EAP.authfile configures the EAP-SIM protocol for a SIM realm:

eapsim.com    -EAP    EAP    "comment"

{  
  EAP-Type SIM

  }  

A3-Algorithm                           "3GPP-Milenage"
A8-Algorithm                           "3GPP-Milenage"
Prefixed-IMSI-Permanent-IDs            "Enabled"
Generic-Permanent-IDs                  "Enabled"
Minimum-Length-IMSI                    6
Maximum-Length-IMSI                    15
Number-Of-Triplets-For-Authentication  2
Protected-Success-Indications          "Disabled"

#           Temporary identity datastores
Fast-Reauth-Lookup   SIMAKA-ReauthCacheLookup   ""
Fast-Reauth-Update   SIMAKA-ReauthCacheUpdate   ""
Pseudonym-Lookup     SIMAKA-PseudonymDecrypt    ""
Pseudonym-Update     NULL                       ""

#           Fast Reauth configuration:
Max-Number-Of-Reauths-Before-Full-Auth-Is-Required  2
Fast-Reauth-Realm                      "this.server.com"
Fast-Reauth-Id-Lifetime                3600

#           Pseudonym configuration:
Pseudonym-Lifetime                     1209600
Generate-Random-Character-Pseudonyms   "No"

}

Global EAP-SIM Configuration in aaa.config

The atv.EAP-SIM{} configuration block, located within the aaa.config file, contains global EAP-SIM configuration information. Some of the parameters represent realm default values for those not specified in the realm configuration. Other parameters represent global defaults which do not correspond to any realm based parameter. For the global parameters common to EAP-SIM and EAP-AKA, see “EAP-AKA and EAP-SIM Common Global Configurations” on page 288.

The following rules apply to the atv.EAP-SIM{} configuration block parameters

- The parameter names are case insensitive.
- For parameters with on/off binary values, the values "enabled", "yes", "on", and "true" are synonyms and the values "disabled", "no", "off", and "false" are synonyms.
- String parameter values should be enclosed in single or double quotes.

The atv.EAP-SIM{} configuration block, in aaa.config file, can contain any subset, including the empty subset, of the following named parameters:
The following parameters are global. No realm configuration overrides.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statistics</td>
<td>This parameter enables/disables the output of EAP-SIM statistics to the logfile when the RAD-Series Server shuts down.</td>
</tr>
</tbody>
</table>
|                   | The valid values are "Enabled" and "Disabled".
|                   | If not explicitly configured, the default value is "Enabled".                                                                                |

The following parameters specify server-wide realm defaults. These are overridable by the realm configuration.

<table>
<thead>
<tr>

A3, A8 and AKA Algorithms

If authentication vectors are not retrieved from a datastore or supplied by an external AuC, then they must be generated using A3 and A8 algorithms for EAP-SIM or the AKA algorithm for EAP-AKA.

GSM A3 and A8 algorithms can be used in EAP-SIM. [GSM-03.20] specifies the general GSM authentication procedure and the external interface (inputs and outputs) of the A3 and A8
algorithms. The operation of these functions falls completely within the domain of an individual network operator, and therefore, the functions are specified by each operator rather than being fully standardized. The GSM-MILENAGE algorithm, specified publicly in [3GPP-TS-55.205], is an example algorithm set for A3 and A8 algorithms.

The AKA algorithm can also use the GSM functions that are used to implement A3 and A8 algorithms mentioned above.

The A3/A8/AKA algorithm plug-ins are located in the AATV directory (/opt/aaa/aatv by default). There may be multiple named A3/A8/AKA algorithms used by the RAD-Series Server. They can be specified in the global configuration file, aaa.config, in the realm-based configurations, or in an users’ profile. See the SDK documentation for information on how to modify the examples or create your own A3/A8/AKA algorithm plug-ins.

**3GPP Milenage A3/A8/AKA Algorithm**

An implementation of the 3GPP Milenage A3/A8 algorithm functions for EAP-SIM authentication and the AKA algorithm for EAP-AKA are included with the RAD-Series Server. The 3GPP Milenage A3/A8/AKA algorithm plug-in module has configuration parameters which allows it to be customized for a specific operator. The A3, A8 and AKA algorithm names, in this plug-in, are 3GPP-Milenage.

See the relevant 3GPP documents for complete details on 3GPP Milenage f1, f1*, f2, f3, f4, f5, f5* algorithms:

- 3GPP TS 35.205 v6.0.0 - General Information
- 3GPP TS 35.206 v6.0.0 - Algorithm Specification
- 3GPP TS 35.207 v6.0.0 - Implementors' Test Data
- 3GPP TS.35.208 v6.0.0 - Design Conformance Test Data
- 3GPP TS.35.909 v6.0.0 - Summary and results of design and evaluation
- 3GPP TS.55.205 v6.2.0 - Authentication and Key Generation functions for A3 and A8

The 3GPP Milenage A3/A8/AKA algorithms are based on the 3GPP Milenage functions:

\[ f_1() , f_{1*}() , f_2() , f_3() , f_4() , f_5() , f_{5*}() \]

A total of 12 parameters are required to fully specify the function set:

- **Ek** 128-bit kernel function
- **OP** 128-bit operator specific value
- **C1-C5** 128-bit values used to compute f1, f1*, f2, f3, f4, f5, f5*
- **R1-R5** integer rotation constants used to compute f1, f1*, f2, f3, f4, f5, f5*

The **Ek** kernel function specified by 3GPP Milenage is 128-bit AES (Rijndael). This plug-in module does not allow the **Ek** kernel function to be changed. The underlying implementation provides support for replacing **Ek**. If replacing the **Ek** kernel function is required, see the SDK documentation for further details.

The 3GPP Milenage A3 algorithm has two variants, corresponding to recommended SRES derivation function #1 and recommended SRES derivation function #2. The A3 function is
affected by the choice, while the A8 function is unaffected. The selection of A3 variant #1 or #2 constitutes another parameter, A3-Variant. The AKA algorithm is unaffected by this parameter.

The selection of parameter values must match the characteristics of the client devices to be authenticated.

Configuration parameters available in aatv.3GPP-Milenage{} block in aaa.config file:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OP</td>
<td>This is a 128-bit operator-specific constant. The OP value MUST be specified by each operator. Milenage specifies no default for this value. If not explicitly configured, the default value is 0x00000000.00000000.00000000.00000000. Use of this value will generate a warning message in the logfile.</td>
</tr>
<tr>
<td>C1</td>
<td>This is a 128-bit computation constant. C1 SHOULD have even parity. Use of a value with odd parity will generate a warning message in the logfile. Milenage specifies the default for this value. If not explicitly configured, the default value is 0x00000000.00000000.00000000.00000000.</td>
</tr>
<tr>
<td>C2</td>
<td>This is a 128-bit computation constant. C2 SHOULD have odd parity. Use of a value with even parity will generate a warning message in the logfile. Milenage specifies the default for this value. If not explicitly configured, the default value is 0x00000000.00000000.00000000.00000000.00000001.</td>
</tr>
<tr>
<td>C3</td>
<td>This is a 128-bit computation constant. C3 SHOULD have odd parity. Use of a value with even parity will generate a warning message in the logfile. Milenage specifies the default for this value. If not explicitly configured, the default value is 0x00000000.00000000.00000000.00000000.00000002.</td>
</tr>
<tr>
<td>C4</td>
<td>This is a 128-bit computation constant. C4 SHOULD have odd parity. Use of a value with even parity will generate a warning message in the logfile. Milenage specifies the default for this value. If not explicitly configured, the default value is 0x00000000.00000000.00000000.00000000.00000000.00000004.</td>
</tr>
</tbody>
</table>
**NOTE:** The $C_i, R_i$ pairs **MUST** be unique. It must **NOT** be the case that both $C_i = C_j$ and $R_i = R_j$ for $i \neq j$. For instance, it must not be the case that both $C_2 = C_4$ and $R_2 = R_4$.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>

Pseudonym and Fast Re-Authentication Data Base AATVs

Pseudonym

The Interlink RAD-Series Server provides a mechanism for EAP-AKA and EAP-SIM, using configured encryption keys, by which pseudonyms can be generated as an encrypted form of the permanent identity, which can be subsequently decrypted to reproduce the permanent identity. Alternatively, the server can generate pseudonyms as a string of random characters, similar to the fast reauthentication identity. In this latter case, an external database is required to store the pseudonym to permanent identity mappings. For many customers, the algorithm based pseudonyms will be the easiest and most efficient choice. The use of random pseudonyms would only be required if the network operator felt the algorithm did not provide adequate hiding of the permanent identity.

In order for pseudonyms to be used, the realm configuration in EAP-Type AKA{} and EAP-Type SIM{} must specify the PseudonymLookup parameter with its value being the name of an AATV which maps the Pseudonym to the permanent identity. The configured AATV may be the Interlink provided one, SIMAKA-PseudonymDecrypt, which does local decryption of a pseudonym using the pseudonym encryption key that was used to encrypt the pseudonym. The configured AATV may also be a customer provided AATV which accesses an external database to map the Pseudonym to the real identity. The requirements of a customer implementation are defined in the Software Developers Kit.

Random Pseudonyms

The RAD-Series Server, when operating in an environment where a central database is used for saving the pseudonym to permanent identity mappings, may be configured to generate a pseudonym as a string of random characters, and store the last-used and last-assigned pseudonyms in this database. The EAP-AKA RFC 4187 and EAP-SIM RFC 4186 recommends saving at least two pseudonyms, the last used and the last assigned. In order for random pseudonyms to work, the realm configuration in EAP-Type AKA{} block and the EAP-Type SIM{} block in the EAP.authfile must specify the Pseudonym-Lookup and Pseudonym-Update parameters with their values being the names of the AATV which maps the pseudonym to the permanent identity and the AATV which stores the random pseudonym in the database. In this case, the pseudonym algorithm would not be employed and the pseudonym would look just like the fast reauthentication identity, with a different prefix. That is: the random pseudonym identity is 10 characters long, consisting of the pseudonym prefix '2' or '4', followed by 9 random characters from the character set {BCDFGHJKLMNPQRSTVWXYZ0123456789}. The random pseudonym has the benefit that there is no way to reverse engineer the permanent identity. It also has the drawback that there must be a database implemented to store and retrieve the mapping of pseudonym to permanent identity.

Algorithm Based Pseudonyms

Interlink has provided an option in the RAD-Series Server that generates a pseudonym by encrypting the real username using an algorithm and an AATV, SIMAKA-PseudonymDecrypt, that decrypts a pseudonym to reproduce the real username. The algorithmic approach has these features/benefits, as specified by Ericsson¹ and submitted to the 3GPP TSG SA WG3 working group:
• No external database is needed to store all the assigned pseudonyms.
• A pseudonym generated on one RADIUS server can be processed by a second RADIUS server.
• No user state is kept in the RADIUS server between WLAN sessions.
• Pseudonyms are not stored in the HSS/HLR.
• Any secret keys used in RADIUS server for the generation of pseudonyms are infeasible to recover (even for an attacker that has available a number of matching permanent identities and pseudonyms).
• Given a pseudonym (or even a number of correlated pseudonyms), it is infeasible for an attacker to recover the corresponding permanent identity.
• It is infeasible for an attacker to determine whether or not two pseudonyms correspond to the same permanent identity.
• No random forgery: It is infeasible for an attacker to generate a valid pseudonym (irrespective of the underlying permanent identity).
• No targeted forgery: It is infeasible for an attacker to generate a valid pseudonym corresponding to a given permanent identity.

In order for the Interlink provided algorithm to be used, the global configuration in \texttt{aatv.SIMAKA{}} must specify one or more \texttt{Pseudonym-Algorithm-Key-n} parameters. The key number specified by "\texttt{Pseudonym-Algorithm-Current-Key}" is used to encrypt new pseudonyms. The other keys are used for decryption of pseudonyms previously generated with these other keys, but are not used for generation of new pseudonyms. With the algorithm based pseudonyms there is no lifetime applied to the pseudonym. A lifetime can be approximated by defining a new key and making the new key the current key, then after the desired lifetime the old key can be removed and the pseudonyms generated with it will be disabled.

When generating a pseudonym based on a permanent identity which is an IMSI, the RAD-Series Server uses a minor modification of an algorithm developed by Ericsson\cite{1} and submitted to the 3GPP TSG SA WG3 working group. In this case, the pseudonym user name is 24 characters long.

When generating a pseudonym based on a permanent identity which is a generic username, e.g. "fred", the RAD-Series Server uses an algorithm derived from the same Ericsson algorithm. In this case, the length of the pseudonym varies, depending on the length of the permanent identity:

• 24 characters if the permanent user name is 1-8 characters.
• 45 characters if the permanent user name is 9-24 characters.
• 66 characters if the permanent user name is 25-40 characters.
• 88 characters if the permanent user name is 41-56 characters.
• 109 characters if the permanent user name is 57-72 characters.
• 130 characters if the permanent user name is 73-88 characters.
• 152 characters if the permanent user name is 89-104 characters.

\textbf{References:}
1. WLAN – Pseudonym Generation for EAP-SIM/AKA, 3GPP, Ericsson, S3-020654.pdf
2. WLAN – Pseudonym Generation for EAP-SIM/AKA, 3GPP, Ericsson, S3-020654.pdf
• 173 characters if the permanent user name is 104-120 characters.
• 194 characters if the permanent user name is 121-136 characters.
• 216 characters if the permanent user name is 137-152 characters.
• 237 characters if the permanent user name is 153-168 characters.
• The pseudonym is not generated if the permanent user name is > 168 characters, as the pseudonym identity would exceed 253 characters.

The RAD-Series Server will generate a pseudonym identity only if the length of the “pseudonym@realrealm” string will not exceed 253 characters.

For a given IMSI permanent identity, there are 56 random user bits involved in the pseudonym generation, resulting in over 7 million trillion (7 \times 10^{18}) different pseudonyms for a given IMSI. The probability that a random forgery decrypts back into anything that looks like an IMSI is less than 1 in 4 million.

For a given non-IMSI permanent identity, there are 32 random user bits involved in the pseudonym generation, resulting in over 4 billion different pseudonyms for a given user. The probability that a random forgery decrypts back into anything that looks like generic username is less than 1 in 50 million.

**Fast Re-Authentication**

Fast re-authentication is a mechanism for a SIM user to freshen his keys periodically. A fast re-authentication, if it is going to take place, will happen in a "short" time after a full authentication or a previous fast re-authentication. If the fast reauthentication identity is assigned and isn't used within this period of time, the fast reauthentication identity and the associated full authentication context is expired.

In order for fast re-authentications to be used, the realm configuration in **EAP-Type AKA** and **EAP-Type SIM** must specify:

- The Fast-Reauth-Update parameter with its value being the name of an AATV which saves the fast reauthentication identity to permanent identity mapping as well as the other fast re-authentication context (the Master Key from the user’s last full authentication, the fast re-authentication counter, and the fast reauthentication identity expiration time).
- The Fast-Reauth-Lookup parameter with its value being the name of an AATV which maps the fast reauthentication identity to the permanent identity and returns the saved context.

The configured AATVs may be the Interlink provided set, **SIMAKA-ReauthCacheUpdate** and **SIMAKA-ReauthCacheLookup**, which do local caching of the fast reauthentication identity to the permanent identity mapping and the necessary attributes. The configured AATVs may also be a customer provided set of AATVs which access an external database to map the fast reauthentication identity to the permanent identity and returns the saved attributes. The requirements of a customer implementation are defined in the Software Developers Kit (SDK).

The Interlink EAP-AKA/SIM RAD-Series Server generates a fast reauthentication identity which is 10 characters long, consisting of the fast reauthentication identity prefix ‘3’ or ‘5’, followed by 9 random characters from the 31 character set consisting of the upper-case characters minus the vowels, plus the 10 digits 0-9, i.e. \{BCDFGHJKLMNPQRSTVWXYZ0123456789\}. 
Since there are 31 choices for each of the 9 random characters, there are then $31^9$ different, i.e. more than 26 trillion, fast reauth identities over the universe of all permanent identities.

Selecting only uppercase characters for the server-generated reauth identities allows for case-insensitive databases lookups.

The RAD-Series Server sends a fast reauthentication identity to the client, which includes a realm. Before generating a fast reauthentication identity, the server first checks that the total length of the “name@realm” string does not exceed 253 characters, the maximum length of a User-Name attribute value. If it is too long, the server does not generate a reauth identity. Since the name portion of the fast reauthentication identity is 10 characters, this problem only occurs if the realm is greater than 242 characters. The realm is either the configured fast reauth realm or the realm from the permanent identity. Recall that a fast reauth realm can be configured for the purpose of targeting a fast reauth authentication request to the specific server which generated the fast reauthentication identity.
